This manual was set on an AUTOLOGIC, Inc. APS-5 phototypesetter driven by the TROFF formatter operating under the UNIX system.

#### INTRODUCTION

This manual describes the programming features of the UNIX system. It provides neither a general overview of the UNIX system nor details of the implementation of the system.

Not all commands, features, and facilities described in this manual are available in every UNIX system. Some of the features require additional utilities which may not exist on your system.

This manual is divided into four sections, some containing interfiled subclasses:

- 2. System Calls.
- 3. Subroutines:
  - 3C. C Programming Language Libraries
  - 3S. Standard I/O Library Routines
  - 3M. Mathematical Library Routines
  - 3X. Specialized Libraries
  - 3F. FORTRAN Programming Libraries
- 4. File Formats.
- 5. Miscellaneous Facilities.

Section 2 (System Calls) describes the entries into the UNIX system kernel, including the C language interface.

Section 3 (Subroutines) describes the available subroutines. Their binary versions reside in various system libraries in the directories /lib and /usr/lib. See intro(3) for descriptions of these libraries and the files in which they are stored.

Section 4 (File Formats) documents the structure of particular kinds of files; for example, the format of the output of the link editor is given in a.out(4). Excluded are files used by only one command (for example, the assembler's intermediate files). In general, the C language struct declarations corresponding to these formats can be found in the directories /usr/include and /usr/include/sys.

Section 5 (Miscellaneous Facilities) contains a variety of things. Included are descriptions of character sets, macro packages, etc.

References with numbers other than those above mean that the utility is contained in the appropriate section of another manual. References with (1) following the command generally mean that the utility is contained in the AT&T 3B2 Computer System User Reference Manual. Those followed by (1M), (7), or (8) are contained in the AT&T 3B2 Computer System Administration Utilities Guide.

Each section consists of a number of independent entries of a page or so each. The name of the entry appears in the upper corners of its pages. Entries within each section are alphabetized, with the exception of the introductory entry that begins each section (also Section 3 is in alphabetical order by suffixes). Some entries may describe several routines, commands, etc. In such cases, the entry appears only once, alphabetized under its "major" name.

All entries are based on a common format, not all of whose parts always appear:

The NAME part gives the name(s) of the entry and briefly states its purpose.

The SYNOPSIS part summarizes the use of the program being described. A few conventions are used, particularly in Section 2 (System Calls):

Boldface strings are literals and are to be typed just as they appear.

*Italic* strings usually represent substitutable argument prototypes and program names found elsewhere in the manual (they are underlined in the typed version of the entries).

Square brackets [] around an argument prototype indicate that the argument is optional. When an argument prototype is given as "name" or "file", it always refers to a *file* name.

Ellipses ... are used to show that the previous argument prototype may be repeated.

A final convention is used by the commands themselves. An argument beginning with a minus -, plus +, or equal sign = is often taken to be some sort of flag argument, even if it appears in a position where a file name could appear. Therefore, it is unwise to have files whose names begin with -, +, or =

The DESCRIPTION part discusses the subject at hand.

The EXAMPLE(S) part gives example(s) of usage, where appropriate.

The FILES part gives the file names that are built into the program.

The SEE ALSO part gives pointers to related information.

The DIAGNOSTICS part discusses the diagnostic indications that may be produced. Messages that are intended to be self-explanatory are not listed.

The WARNINGS part points out potential pitfalls.

The BUGS part gives known bugs and sometimes deficiencies. Occasionally, the suggested fix is also described.

A table of contents and a permutted index derived from that table precede Section 2. On each *index* line, the title of the entry to which that line refers is followed by the appropriate section number in parentheses. This is important because there is considerable duplication of names among the sections, arising principally from commands that exist only to exercise a particular system call.

A Permuted Index follows the Introduction and Table of Contents. The Permuted Index is used by searching the middle column for a key word or phrase. The right column will then contain the name of the manual page that contains that command. The left column contains additional useful information about the command.

# TABLE OF CONTENTS

# 2. System Calls

intro introduction to system calls and error numbers
access determine accessibility of a file
acct enable or disable process accounting
acct enable or disable process accounting alarm
brk
brk
chmod
change owner and group of a file
chown
close
close
creat create a new file or rewrite an existing one
dup duplicate an open file descriptor
exec
exit
fcntl
fork
getpid get process, process group, and parent process IDs
getuid get real user, effective user, real group, and effective group IDs
ioctl
kill send a signal to a process or a group of processes
link
lseek move read/write file pointer
mknod make a directory, or a special or ordinary file
mount
msgctl message control operations
msgget
msgget
msgop
nice
open open for reading or writing
pause suspend process until signal
pipe
plock lock process, text, or data in memory
profil execution time profile
ptrace
read
semanhore control operations
semget
semget
setpgrp set process group ID
setuid set user and group IDs
setuid set user and group IDs shmctl shared memory control operations
shmget
shmon shared memory operations
shmop
stat
sync
sys3b
time
times get process and child process times
uadmin administrative control
ulimit
umask set and get file creation mask
umount

get name of current UNIX system
remove directory entry
get file system statistics
et file access and modification times
or child process to stop or terminate
write on a file

# 3. Subroutines

intro introduction to subroutines and libraries
C PROGRAMMING LANGUAGE UTILITIES
a641 convert between long integer and base-64 ASCII string
abort
abs return integer absolute value
bsearch binary search a sorted table
clock report CPU time used
conv
crypt generate hashing encryption
ctermid generate file name for terminal
ctime
ctype
cuserid get character login name of the user
dial establish an outgoing terminal line connection
drand48 generate uniformly distributed pseudo-random numbers
ecvt convert floating-point number to string
end last locations in program
fclose
ferror
fopen
fread binary input/output
frexp manipulate parts of floating-point numbers
fseek reposition a file pointer in a stream
ftw
getc get character or word from a stream
getcwd get path-name of current working directory
getenv return value for environment name
getgrent get group file entry
getlogin
getopt get option letter from argument vector
getpass
getpw get name from UID
getpwent get password file entry
gets
getut
hsearch manage hash search tables
13tol convert between 3-byte integers and long integers
lockf record locking on files
lsearch linear search and update
malloc
memory
mktemp
monitor
nlist
perror
popen initiate pipe to/from a process
printf
putc
putenv

putpwent
tmpnam create a name for a temporary file
tsearch manage binary search trees ttyname
ttyslot find the slot in the utmp file of the current user
ungetc
vprintf print formatted output of a varargs argument list
MATH LIBRARIES
bessel
erf error function and complementary error function
exp exponential, logarithm, power, square root functions
floor floor, ceiling, remainder, absolute value functions
gamma log gamma function hypot
matherr error-handling function
matherr
trig trigonometric functions
trig
assert verify program assertion
curses
ldahread read the archive header of a member of an archive file
ldclose
ldfhread read the file header of a common object file ldgetname retrieve symbol name for common object file symbol table entry
Idlread manipulate line number entries of a common object file function
Idlseek seek to line number entries of a section of a common object file
Idohseek seek to the optional file header of a common object file
ldopen open a common object file for reading
ldrseek seek to relocation entries of a section of a common object file
ldshread read an indexed/named section header of a common object file
ldsseek seek to an indexed/named section of a common object file
ldtbindex compute the index of a symbol table entry of a common object file
ldtbread read an indexed symbol table entry of a common object file
ldtbseek seek to the symbol table of a common object file
logname return login name of user malloc fast main memory allocator
plot graphics interface subroutines
regcmp compile and execute regular expression
sputl access long integer data in a machine-independent fashion
vprintf print formatted output of a varargs argument list

FORTRAN	PROGRAMMING LIBRARIES
abort	· · · · · · · · · · · · · · · · · · ·
abs	
acos	· · · · · · · · · · · · · · · · · · ·
aimag	Fortran imaginary part of complex argument
aint	· · · · · · · · · · · · · · · · · Fortran integer part intrinsic function
asin	· · · · · · · · · · · · · · · · · Fortran arcsine intrinsic function
atan	Fortran arctangent intrinsic function
atan2	· · · · · · · · · · · · · · · · Fortran arctangent intrinsic function
bool	· · · · · · · · · · · · · · · · · Fortran bitwise Boolean functions
conjg	· · · · · · · · Fortran complex conjugate intrinsic function
cos	Fortran cosine intrinsic function
cosh	· · · · · · · · · Fortran hyperbolic cosine intrinsic function
dim	positive difference intrinsic functions
dprod	· · · · · · · · double precision product intrinsic function
exp	· · · · · · · · · · · · · Fortran exponential intrinsic function
ftype	• • • • • • • • • • • • • • • • explicit Fortran type conversion
getarg	· · · · · · · · · · · · return Fortran command-line argument
getenv .	· · · · · · · · · · · · · · · · · return Fortran environment variable
index	return the number of command line arguments
linuex	return location of Fortran substring
log	return length of Fortran string Fortran natural logarithm intrinsic function
log 1	Fortran common logarithm intrinsic function
max	Fortran maximum-value functions
mclock .	· · · · · · · · · · · · · · · · · return Fortran time accounting
mil	bit field manipulation intrinsic function and subroutines
min	· · · · · · · · · · · · · · · · · · ·
mod	· · · · · · · · · · · · · Fortran remaindering intrinsic functions
rand	
round	· · · · · · · · · · · · · · · · · · ·
sign	· · · · · · · · · Fortran transfer-of-sign intrinsic function
signal	specify Fortran action on receipt of a system signal
SIN	Fortran sine intrinsic function Fortran hyperbolic sine intrinsic function
SIIII	Fortran hyperbolic sine intrinsic function
sqrt	Fortran square root intrinsic function string comparison intrinsic functions
suchip	issue a shell command from Fortran
tan	Fortran tangent intrinsic function
tanh	Fortran hyperbolic tangent intrinsic function
***************************************	The state of the s

### PERMUTED INDEX

13tol, Itol3: convert between	3-byte integers and long/ 13tol(3C)	
long integer and base-64/	a64l, l64a: convert between a64l(3C)	
	abort: generate an IOT fault abort(3C)	
program.	abort: terminate Fortran abort(3F)	
Fortran absolute value.	abs, iabs, dabs, cabs, zabs: abs(3F)	
value.	abs: return integer absolute abs(3C)	
abs: return integer	absolute value abs(3C)	
dabs, cabs, zabs: Fortran	absolute value. abs, iabs, abs(3F)	
/floor, ceiling, remainder,	absolute value functions floor(3M)	
utime: set file	access and modification times utime(2)	
accessibility of a file.	access: determine access(2)	
sputl, sgetl:	access long integer data in a/ sputl(3X)	
ldfcn: common object file	access routines ldfcn(4)	
/setutent, endutent, utmpname:	access utmp file entry getut(3C)	
access: determine	accessibility of a file access (2)	
enable or disable process	accounting. acct: acct(2)	
mclock: return Fortran time	accounting mclock(3F)	
process accounting.	acct: enable or disable acct(2)	
sin, cos, tan, asin,	acos, atan, atan2:/ trig(3M)	
intrinsic function.	acos, dacos: Fortran arccosine acos(3F)	
putenv: change or	add value to environment putenv(3C)	
uadmin:	administrative control uadmin(2)	
imaginary part of complex/	aimag, dimag: Fortran aimag(3F)	
part intrinsic function.	aint, dint: Fortran integer aint(3F)	
alarm: set a process	alarm clock alarm(2)	
clock.	alarm: set a process alarm alarm(2)	
change data segment space	allocation. brk, sbrk: brk(2)	
realloc, calloc: main memory	allocator. malloc, free, malloc(3C)	
mallinfo: fast main memory	allocator. /calloc, mallopt, malloc(3X)	
natural logarithm/ log,	alog, dlog, clog: Fortran log(3F)	
logarithm intrinsic/ log10,	alog10, dlog10: Fortran common log10(3F)	
Fortran/ max, max0,	amax0, max1, amax1, dmax1: max(3F)	
max, max0, amax0, max1,	amax1, dmax1: Fortran/ max(3F)	
Fortran/ min, min0,	amin0, min1, amin1, dmin1: min(3F)	
min, min0, amin0, min1,	amin1, dmin1: Fortran/ min(3F)	
remaindering intrinsic/ mod,	amod, dmod: Fortran mod(3F)	
rshift: Fortran bitwise/	and, or, xor, not, lshift, bool(3F)	
Fortran nearest integer/	anint, dnint, nint, idnint: round(3F)	
format.	ar: common archive file ar(4)	
acos, dacos: Fortran	arccosine intrinsic function acos(3F)	
cpio: format of cpio	archive cpio(4)	
ar: common	archive file format ar(4)	
header of a member of an	archive file. /the archive ldahread(3X)	
an archive/ ldahread: read the	archive header of a member of ldahread(3X)	,
asin, dasin: Fortran	arcsine intrinsic function asin(3F)	
atan2, datan2: Fortran	arctangent intrinsic function atan2(3F)	
atan, datan: Fortran	arctangent intrinsic function atan(3F)	
imaginary part of complex return Fortran command-line	argument. /dimag: Fortran aimag(3F)	
	argument. getarg: getarg(3F)

j0, j1, jn, y0, y1, yn:	Bessel functions	 bessel(3M)
fread, fwrite:	binary input/output	 fread(3S)
bsearch:	binary search a sorted table	
tfind, tdelete, twalk: manage	binary search trees. tsearch,	
btest, ibset, ibclr, mvbits:	bit. /and subroutines.,	
/not, lshift, rshift: Fortran	bitwise Boolean functions	
sync: update super	block	
rshift: Fortran bitwise	Boolean functions. /lshift,	
space allocation.	brk, sbrk: change data segment	
sorted table.	bsearch: binary search a	
/functions and subroutines.,	btest, ibset, ibclr, mvbits:/	
stdio: standard	buffered input/output package	
setbuf, setvbuf: assign	buffering to a stream.	
swab: swap	bytes	
value. abs, iabs, dabs, data returned by stat system	cabs, zabs: Fortran absolute	
malloc, free, realloc,	call. stat:	
fast/ malloc, free, realloc,	calloc: main memory allocator calloc, mallopt, mallinfo:	
intro: introduction to system	calls and error numbers.	
terminfo: terminal	capability data base.	
pnch: file format for	card images.	
function. cos, dcos,	ccos: Fortran cosine intrinsic	A STATE OF THE STA
ceiling, remainder,/ floor,	ceil, fmod, fabs: floor,	
/ceil, fmod, fabs: floor,	ceiling, remainder, absolute/	
intrinsic/ exp, dexp,	cexp: Fortran exponential	
pipe: create an interprocess	channel	
/dble, cmplx, dcmplx, ichar,	char: explicit Fortran type/	
stream. ungetc: push	character back into input	 ungetc(3S)
user. cuserid: get	character login name of the	 cuserid(3S)
/getchar, fgetc, getw: get	character or word from a/	 getc(3S)
/putchar, fputc, putw: put	character or word on a stream	
ascii: map of ASCII	character set.	
_tolower, toascii: translate	characters. /_toupper,	
iscntrl, isascii: classify	characters. /isprint, isgraph,	
directory.	chdir: change working	
systems processed by fsck.	checklist: list of file	
	child process times	
terminate. wait: wait for	child process to stop or	
of a file.	chmod: change mode of file	
or a me.	chroot: change root directory	
isgraph, iscntrl, isascii:	classify characters. /isprint,	
status/ ferror, feof,	clearerr, fileno: stream	
alarm: set a process alarm	clock.	
and the deprocess within	clock: report CPU time used	
logarithm/ log, alog, dlog,	clog: Fortran natural	Section 1997 Market 1997
ldclose, ldaclose:	close a common object file.	
close:	close a file descriptor.	
descriptor.	close: close a file	
fclose, fflush:	close or flush a stream	fclose(3S)
/real, float, sngl, dble,	cmplx, dcmplx, ichar, char:/	
		ALC 200

system: issue a shell	command from Fortran				system(3F)

core: format of	core image file				core(4)
cosine intrinsic function.	cos, dcos, ccos: Fortran				cos(3F)
atan2: trigonometric/ sin,	cos, tan, asin, acos, atan,				trig(3M)
hyperbolic cosine intrinsic/	cosh, dcosh: Fortran				cosh(3F)
functions. sinh,	cosh, tanh: hyperbolic				sinh(3M)
cos, dcos, ccos: Fortran	cosine intrinsic function				cos(3F)

/dcosh: Fortran hyperbolic	cosine intrinsic function cosh(3F)
cpio: format of	cpio archive cpio(4)
	cpio: format of cpio archive cpio(4)
clock: report	CPU time used clock(3C)
rewrite an existing one.	creat: create a new file or creat(2)
file. tmpnam, tempnam:	create a name for a temporary tmpnam(3S)
an existing one. creat:	create a new file or rewrite creat(2)
fork:	create a new process fork(2)
tmpfile:	create a temporary file tmpfile(3S)
channel. pipe:	create an interprocess pipe(2)
umask: set and get file	creation mask umask(2)
optimization package. curses:	CRT screen handling and curses (3X)
generate hashing encryption.	crypt, setkey, encrypt: crypt(3C)
function. sin, dsin,	csin: Fortran sine intrinsic sin(3F)
intrinsic/ sqrt, dsqrt,	csqrt: Fortran square root sqrt(3F)
for terminal.	ctermid: generate file name ctermid(3S)
asctime, tzset: convert date/	ctime, localtime, gmtime, ctime(3C)
uname: get name of	current UNIX system uname(2)
slot in the utmp file of the	current user. /find the ttyslot(3C)
getcwd: get path-name of	current working directory getcwd(3C)
and optimization package.	curses: CRT screen handling curses(3X)
name of the user.	cuserid: get character login cuserid(3S)
absolute value. abs, iabs,	dabs, cabs, zabs: Fortran abs(3F)
intrinsic function. acos,	dacos: Fortran arccosine acos(3F)
intrinsic function, asin,	dasin: Fortran arcsine asin(3F)
terminfo: terminal capability	data base terminfo(4)
/sgetl: access long integer	data in a machine-independent/ sputl(3X)
plock: lock process, text, or	data in memory plock(2)
call. stat:	data returned by stat system stat(5)
brk, sbrk: change	data segment space allocation brk(2)
types: primitive system	data types types(5)
master: master configuration	database master (4)
intrinsic function. atan,	datan: Fortran arctangent atan(3F)
intrinsic function. atan2,	datan2: Fortran arctangent atan2(3F)
/asctime, tzset: convert	date and time to string ctime(3C)
/idint, real, float, sngl,	dble, cmplx, dcmplx, ichar,/ ftype(3F)
/float, sngl, dble, cmplx,	dcmplx, ichar, char: explicit/ ftype(3F)
conjugate intrinsic/ conjg,	dconig: Fortran complex conjg(3F)
intrinsic function. cos,	dcos, ccos: Fortran cosine cos(3F)
cosine intrinsic/ cosh,	dcosh: Fortran hyperbolic cosh(3F)
difference intrinsic/ dim,	ddim, idim: positive dim(3F)
timezone: set	default system time zone timezone(4)
close: close a file	descriptor close(2)
dup: duplicate an open file	descriptor dup(2)
file. access:	determine accessibility of a access(2)
ioctl: control	device ioctl(2)
exponential intrinsic/ exp,	dexp, cexp: Fortran exp(3F)
terminal line connection.	dial: establish an out-going dial(3C)
dim, ddim, idim: positive	difference intrinsic/ dim(3F)
difference intrinsic/	dim, ddim, idim: positive dim(3F)
of complex argument. aimag,	dimag: Fortran imaginary part aimag(3F)
intrinsic function. aint,	dint: Fortran integer part aint(3F)
intrinsic function. aint,	dir: format of directories dir(4)
dir: format of	directories dir(4)
chdir: change working	directory
chroot: change root	directory
unlink: remove	
path-name of current working	directory, getcwd: get getcwd(3C) directory, or a special or mknod(2)
ordinary file. mknod: make a	
acct: enable or	
hypot: Euclidean	distance function hypot(3M)
/lcong48: generate uniformly	distributed pseudo-random/ drand48(3C)
logarithm/ log, alog,	dlog, clog: Fortran natural log(3F)
logarithm/ log10, alog10,	dlog10: Fortran common log10(3F)

may may() amay() may() amay()	dmax1: Fortran maximum-value/ max(3F)
max, max0, amax0, max1, amax1,	dmin1: Fortran minimum-value/ min(3F)
min, min0, amin0, min1, amin1,	
intrinsic/ mod, amod,	dmod: Fortran remaindering mod(3F)
nearest integer/ anint,	dnint, nint, idnint: Fortran round(3F)
intrinsic function. dprod:	double precision product dprod(3F)
/atof: convert string to	double-precision number strtod(3C)
product intrinsic function.	dprod: double precision dprod(3F)
nrand48, mrand48, jrand48,/	drand48, erand48, lrand48, drand48(3C)
transfer-of-sign/ sign, isign,	dsign: Fortran sign(3F)
intrinsic function. sin,	dsin, csin: Fortran sine sin(3F)
intrinsic function. sinh,	dsinh: Fortran hyperbolic sine sinh(3F)
root intrinsic/ sqrt,	dsqrt, csqrt: Fortran square sqrt(3F)
intrinsic function. tan,	dtan: Fortran tangent tan(3F)
tangent intrinsic/ tanh,	dtanh: Fortran hyperbolic tanh(3F)
descriptor.	dup: duplicate an open file dup(2)
descriptor. dup:	duplicate an open file dup(2)
floating-point number to/	ecvt, fcvt, gcvt: convert ecvt(3C)
program. end, etext,	edata: last locations in end(3C)
common assembler and link	editor output. a.out: a.out(4)
/user, real group, and	effective group IDs getuid(2)
and//getegid: get real user,	effective user, real group, getuid(2)
accounting. acct:	enable or disable process acct(2)
encryption. crypt, setkey,	encrypt: generate hashing crypt(3C)
encrypt: generate hashing	encryption. crypt, setkey, crypt(3C)
locations in program.	end, etext, edata: last end(3C)
/getgrgid, getgrnam, setgrent,	endgrent, fgetgrent: get group/ getgrent(3C)
/getpwuid, getpwnam, setpwent,	endpwent, fgetpwent: get/ getpwent(3C)
utmp//pututline, setutent,	endutent, utmpname: access getut(3C)
nlist: get	entries from name list nlist(3C)
file. linenum: line number	entries in a common object linenum(4)
file//manipulate line number	
/IdnIseek: seek to line number	entries of a section of a/
/ldnrseek: seek to relocation	entries of a section of a/ ldrseek(3X)
utmp, wtmp: utmp and wtmp	entry formats utmp(4)
fgetgrent: get group file	entry. /setgrent, endgrent, getgrent(3C)
fgetpwent: get password file	entry. /setpwent, endpwent, getpwent(3C)
utmpname: access utmp file	entry. /setutent, endutent, getut(3C)
object file symbol table	entry. /symbol name for common ldgetname(3X)
/the index of a symbol table	entry of a common object file ldtbindex(3X)
/read an indexed symbol table	entry of a common object file ldtbread(3X)
putpwent: write password file	entry putpwent(3C)
unlink: remove directory	entry unlink(2)
	environ: user environment environ(5)
environ: user	environment environ(5)
getenv: return value for	environment name getenv(3C)
putenv: change or add value to	environment putenv(3C)
getenv: return Fortran	environment variable getenv(3F)
mrand48, jrand48,/ drand48,	erand48, lrand48, nrand48, drand48(3C)
complementary error function.	erf, erfc: error function and erf(3M)
complementary error/ erf,	erfc: error function and erf(3M)
system error/ perror,	errno, sys_errlist, sys_nerr: perror(3C)
complementary/ erf, erfc:	error function and erf(3M)
function and complementary	error function. /erfc: error erf(3M)
sys_errlist, sys_nerr: system	error messages. /errno, perror(3C)
to system calls and	error numbers. /introduction intro(2)
matherr:	error-handling function matherr(3M)
terminal line/ dial:	establish an out-going dial(3C)
in program. end,	etext, edata: last locations end(3C)
hypot:	Euclidean distance function hypot(3M)
execlp, execvp: execute a/	execl, execv, execle, execve, exec(2)
execvp: execute/ execl, execv,	execle, execve, execlp, exec(2)
exect, exect, exect, exect,	,, c.co.p,
,, oncoio, oncoro,	execlp, execup; execute a/ exec(2)
execve execln execvn	execlp, execute a/ exec(2) execute a file. /execle exec(2)
execve, execlp, execvp: regcmp, regex: compile and	execlp, execvp: execute a/ exec(2) execute a file. /execle, exec(2) execute regular expression regcmp(3X)

sleep: suspend	execution for interval sleep(3C)
monitor: prepare	execution profile monitor (3C)
profil:	execution time profile profil(2)
execvp: execute a/ execl,	execv, execle, execve, execlp, exec(2)
execute/ execl, execv, execle,	execve, execlp, execvp: exec(2)
/execv, execle, execve, execlp,	execvp: execute a file exec(2)
a new file or rewrite an	existing one. creat: create creat(2)
process.	exit, exit: terminate exit(2)
exit,	_exit: terminate process exit(2)
exponential intrinsic/	exp, dexp, cexp: Fortran exp(3F)
exponential, logarithm,/	exp, log, log10, pow, sqrt: exp(3M)
cmplx, dcmplx, ichar, char:	explicit Fortran type//dble, ftype(3F)
exp, dexp, cexp: Fortran	exponential intrinsic/ exp(3F)
exp, log, log10, pow, sqrt:	exponential, logarithm, power,/ exp(3M)
routines. regexp: regular	expression compile and match regexp(5)
compile and execute regular	expression. regcmp, regex: regcmp(3X)
remainder,/ floor, ceil, fmod,	fabs: floor, ceiling,
data in a machine-independent	fashion /access long integer sputl(3X)
/calloc, mallopt, mallinfo:	fast main memory allocator malloc(3X)
abort: generate an IOT	fault abort(3C)
a stream.	fclose, fflush: close or flush fclose(3S)
	fcntl: file control fcntl(2)
	fcntl: file control options fcntl(5)
floating-point number/ ecvt,	fcvt, gcvt: convert ecvt(3C)
fopen, freopen,	fdopen: open a stream fopen(3S)
status inquiries. ferror,	feof, clearerr, fileno: stream ferror(3S)
fileno: stream status/	ferror, feof, clearerr, ferror(3S)
stream. fclose,	fflush: close or flush a fclose(3S)
word from a/ getc, getchar,	fgetc, getw: get character or getc(3S)
/getgrnam, setgrent, endgrent,	fgetgrent: get group file/ getgrent(3C)
/getpwnam, setpwent, endpwent,	fgetpwent: get password file/ getpwent(3C)
stream. gets,	fgets: get a string from a gets(3S)
times. utime: set	file access and modification utime(2)
determine accessibility of a	file access routines
chmod: change mode of	file. access:
change owner and group of a	file. chown:
fcntl:	
fentl:	file control options fcntl(2)
core: format of core image	file core(4)
umask: set and get	file creation mask umask(2)
close: close a	file descriptor
dup: duplicate an open	file descriptor dup(2)
endgrent, fgetgrent: get group	file entry. /setgrent, getgrent(3C)
fgetpwent: get password	file entry. /endpwent, getpwent(3C)
utmpname: access utmp	file entry. /endutent, getut(3C)
putpwent: write password	file entry putpwent(3C)
execlp, execvp: execute a	file. /execv, execle, execve, exec(2)
Idaopen: open a common object	file for reading. ldopen, ldopen(3X)
ar: common archive	file format ar(4)
pnch:	file format for card images pnch(4)
intro: introduction to	file formats intro(4)
entries of a common object	file function. /line number Idlread(3X)
group: group	file group(4)
files. filehdr:	file header for common object filehdr(4)
file. ldfhread: read the	file header of a common object ldfhread(3X)
ldohseek: seek to the optional	file header of a common object/ ldohseek(3X)
issue: issue identification	file issue(4)
of a member of an archive	file. /read the archive header ldahread(3X)
close a common object	file. Idclose, Idaclose: Idclose(3X)
file header of a common object	file. ldfhread: read the ldfhread(3X)
a section of a common object	file. /line number entries of Idlseek(3X)
file header of a common object	file. /seek to the optional Idohseek(3X)
a section of a common object	file. /relocation entries of ldrseek(3X)

hander of a common chiest	flo /indexed/nemed section Idebrood(2V)
header of a common object	file. /indexed/named section ldshread(3X)
section of a common object	file. /to an indexed/named ldsseek(3X)
table entry of a common object	file. /the index of a symbol ldtbindex(3X)
table entry of a common object	file. /read an indexed symbol ldtbread(3X)
table of a common object	file. /seek to the symbol ldtbseek(3X)
entries in a common object	file. linenum: line number linenum(4)
link: link to a	file link(2)
or a special or ordinary	file. /make a directory, mknod(2)
ctermid: generate	file name for terminal ctermid(3S)
mktemp: make a unique	file name mktemp(3C)
/find the slot in the utmp	file of the current user
one. creat: create a new	file or rewrite an existing creat(2) file passwd(4)
passwd: password	1
/rewind, ftell: reposition a lseek: move read/write	
read: read from	file pointer lseek(2) file read(2)
for a common object	
scessile: format of SCCS	file. /relocation information reloc(4) file sccsfile(4)
header for a common object	
stat, fstat: get	(-)
/symbol name for common object	
syms: common object	file symbol table entry ldgetname(3X) file symbol table format syms(4)
volume.	file system: format of system fs(4)
mount: mount a	file system mount(2)
ustat: get	file system statistics ustat(2)
mnttab: mounted	file system table mnttab(4)
umount: unmount a	file system umount(2)
fsck. checklist: list of	file systems processed by
term: format of compiled term	file term(4)
tmpfile: create a temporary	file tmpfile(3S)
create a name for a temporary	file. tmpnam, tempnam: tmpnam(3S)
ftw: walk a	file tree ftw(3C)
write: write on a	file write(2)
common object files.	filehdr: file header for filehdr(4)
ferror, feof, clearerr,	fileno: stream status/ ferror(3S)
file header for common object	files. filehdr: filehdr(4)
format specification in text	files. fspec: fspec(4)
string, format of graphical	files. /graphical primitive gps(4)
lockf: record locking on	files lockf(3C)
ttyname, isatty:	find name of a terminal ttyname(3C)
of the current user, ttyslot:	ma name of a terminar.
	find the slot in the utmp file ttyslot(3C)
int, ifix, idint, real,	The state of the s

INTRO(2) INTRO(2)

NAME

intro - introduction to system calls and error numbers

#### **SYNOPSIS**

#include <errno.h>

#### DESCRIPTION

This section describes all of the system calls. Most of these calls have one or more error returns. An error condition is indicated by an otherwise impossible returned value. This is almost always -1; the individual descriptions specify the details. An error number is also made available in the external variable errno. Errno is not cleared on successful calls, so it should be tested only after an error has been indicated.

Each system call description attempts to list all possible error numbers. The following is a complete list of the error numbers and their names as defined in <errno.h>.

#### 1 EPERM Not owner

Typically this error indicates an attempt to modify a file in some way forbidden except to its owner or super-user. It is also returned for attempts by ordinary users to do things allowed only to the super-user.

#### 2 ENOENT No such file or directory

This error occurs when a file name is specified and the file should exist but doesn't, or when one of the directories in a path name does not exist.

#### 3 ESRCH No such process

No process can be found corresponding to that specified by pid in kill or ptrace.

## 4 EINTR Interrupted system call

An asynchronous signal (such as interrupt or quit), which the user has elected to catch, occurred during a system call. If execution is resumed after processing the signal, it will appear as if the interrupted system call returned this error condition.

### 5 EIO I/O error

Some physical I/O error has occurred. This error may in some cases occur on a call following the one to which it actually applies.

#### 6 ENXIO No such device or address

I/O on a special file refers to a subdevice which does not exist, or beyond the limits of the device. It may also occur when, for example, a tape drive is not on-line or no disk pack is loaded on a drive.

#### 7 E2BIG Arg list too long

An argument list longer than 5,120 bytes is presented to a member of the exec family.

#### 8 ENOEXEC Exec format error

A request is made to execute a file which, although it has the appropriate permissions, does not start with a valid magic number (see a.out (4)).

#### 9 EBADF Bad file number

Either a file descriptor refers to no open file, or a read (respectively, write) request is made to a file which is open only for writing (respectively, reading).

### 10 ECHILD No child processes

A wait was executed by a process that had no existing or unwaited-for child processes.

INTRO(2)

11 EAGAIN No more processes

A fork failed because the system's process table is full or the user is not allowed to create any more processes.

12 ENOMEM Not enough space

During an exec, brk, or sbrk, a program asks for more space than the system is able to supply. This is not a temporary condition; the maximum space size is a system parameter. The error may also occur if the arrangement of text, data, and stack segments requires too many segmentation registers, or if there is not enough swap space during a fork.

13 EACCES Permission denied

An attempt was made to access a file in a way forbidden by the protection system.

14 EFAULT Bad address

The system encountered a hardware fault in attempting to use an argument of a system call.

15 ENOTBLK Block device required

A non-block file was mentioned where a block device was required, e.g., in mount.

16 EBUSY Device or resource busy

An attempt was made to mount a device that was already mounted or an attempt was made to dismount a device on which there is an active file (open file, current directory, mounted-on file, active text segment). It will also occur if an attempt is made to enable accounting when it is already enabled. The device or resource is currently unavailable.

17 EEXIST File exists

An existing file was mentioned in an inappropriate context, e.g., link.

18 EXDEV Cross-device link

A link to a file on another device was attempted.

19 ENODEV No such device

An attempt was made to apply an inappropriate system call to a device; e.g., read a write-only device.

20 ENOTDIR Not a directory

A non-directory was specified where a directory is required, for example in a path prefix or as an argument to *chdir*(2).

21 EISDIR Is a directory

An attempt was made to write on a directory.

22 EINVAL Invalid argument

Some invalid argument (e.g., dismounting a non-mounted device; mentioning an undefined signal in *signal*, or *kill*; reading or writing a file for which *lseek* has generated a negative pointer). Also set by the math functions described in the (3M) entries of this manual.

23 ENFILE File table overflow

The system file table is full, and temporarily no more opens can be accepted.

24 EMFILE Too many open files

No process may have more than 20 file descriptors open at a time. When a record lock is being created with *fcntl*, there are too many files with record locks on them.

25 ENOTTY Not a character device

An attempt was made to ioctl(2) a file that is not a special character

INTRO(2)

device.

26 ETXTBSY Text file busy

An attempt was made to execute a pure-procedure program that is currently open for writing. Also an attempt to open for writing a pure-procedure program that is being executed.

27 EFBIG File too large

The size of a file exceeded the maximum file size (1,082,201,088 bytes) or ULIMIT: see *ulimit* (2).

28 ENOSPC No space left on device

During a write to an ordinary file, there is no free space left on the device. In fcntl, the setting or removing of record locks on a file cannot be accomplished because there are no more record entries left on the system.

29 ESPIPE Illegal seek

An lseek was issued to a pipe.

30 EROFS Read-only file system

An attempt to modify a file or directory was made on a device mounted read-only.

31 EMLINK Too many links

An attempt to make more than the maximum number of links (1000) to a file.

32 EPIPE Broken pipe

A write on a pipe for which there is no process to read the data. This condition normally generates a signal; the error is returned if the signal is ignored.

33 EDOM Math argument

The argument of a function in the math package (3M) is out of the domain of the function.

34 ERANGE Result too large

The value of a function in the math package (3M) is not representable within machine precision.

35 ENOMSG No message of desired type

An attempt was made to receive a message of a type that does not exist on the specified message queue; see msgop (2).

36 EIDRM Identifier Removed

This error is returned to processes that resume execution due to the removal of an identifier from the file system's name space (see msgctl(2), semctl(2), and shmctl(2)).

45 EDEADLK Deadlock

A deadlock situation was detected and avoided.

#### **Definitions**

Process ID Each active process in the system is uniquely identified by a positive integer called a process ID. The range of this ID is from 1 to 30,000.

Parent Process ID A new process is created by a currently active process; see fork(2). The parent process ID of a process is the process ID of its creator.

Process Group ID Each active process is a member of a process group that is identified by a positive integer called the process group ID. This ID is the process ID of the group leader. This grouping permits the signaling of related

INTRO(2) INTRO(2)

processes; see kill(2).

Tty Group ID Each active process can be a member of a terminal group that is identified by a positive integer called the tty group ID. This grouping is used to terminate a group of related processes upon termination of one of the processes in the group; see *exit*(2) and *signal*(2).

Real User ID and Real Group ID Each user allowed on the system is identified by a positive integer called a real user ID.

Each user is also a member of a group. The group is identified by a positive integer called the real group ID.

An active process has a real user ID and real group ID that are set to the real user ID and real group ID, respectively, of the user responsible for the creation of the process.

Effective User ID and Effective Group ID An active process has an effective user ID and an effective group ID that are used to determine file access permissions (see below). The effective user ID and effective group ID are equal to the process's real user ID and real group ID respectively, unless the process or one of its ancestors evolved from a file that had the set-user-ID bit or set-group ID bit set; see exec(2).

Super-user A process is recognized as a *super-user* process and is granted special privileges if its effective user ID is 0.

Special Processes The processes with a process ID of 0 and a process ID of 1 are special processes and are referred to as *proc0* and *proc1*.

*Proc0* is the scheduler. *Proc1* is the initialization process (*init*). Proc1 is the ancestor of every other process in the system and is used to control the process structure.

File Descriptor A file descriptor is a small integer used to do I/O on a file. The value of a file descriptor is from 0 to 19. A process may have no more than 20 file descriptors (0-19) open simultaneously. A file descriptor is returned by system calls such as open(2), or pipe(2). The file descriptor is used as an argument by calls such as read(2), write(2), ioctl(2), and close(2).

File Name Names consisting of 1 to 14 characters may be used to name an ordinary file, special file or directory.

These characters may be selected from the set of all character values excluding \0 (null) and the ASCII code for / (slash).

Note that it is generally unwise to use \*, ?, [, or ] as part of file names because of the special meaning attached to these characters by the shell. See sh(1). Although permitted, it is advisable to avoid the use of unprintable characters in file names.

Path Name and Path Prefix A path name is a null-terminated character string starting with an optional slash (/), followed by zero or more directory names separated by slashes, optionally followed by a file name.

More precisely, a path name is a null-terminated character string constructed as follows:

```
<path-name>::=<file-name>|<path-prefix><file-name>|/
<path-prefix>::=<rtprefix>|/<rtprefix>
<rtprefix>::=<dirname>/|<rtprefix><dirname>/
```

where <file-name> is a string of 1 to 14 characters other than the ASCII slash and null, and <dirname> is a string of 1 to 14 characters (other than the ASCII slash and null) that names a directory.

If a path name begins with a slash, the path search begins at the *root* directory. Otherwise, the search begins from the current working directory.

A slash by itself names the root directory.

Unless specifically stated otherwise, the null path name is treated as if it named a non-existent file.

# Directory

Directory entries are called links. By convention, a directory contains at least two links, . and .., referred to as *dot* and *dot-dot* respectively. Dot refers to the directory itself and dot-dot refers to its parent directory.

Root Directory and Current Working Directory Each process has associated with it a concept of a root directory and a current working directory for the purpose of resolving path name searches. The root directory of a process need not be the root directory of the root file system.

#### File Access Permissions

Read, write, and execute/search permissions on a file are granted to a process if one or more of the following are true:

The effective user ID of the process is super-user.

The effective user ID of the process matches the user ID of the owner of the file and the appropriate access bit of the "owner" portion (0700) of the file mode is set.

The effective user ID of the process does not match the user ID of the owner of the file, and the effective group ID of the process matches the group of the file and the appropriate access bit of the "group" portion (070) of the file mode is set.

The effective user ID of the process does not match the user ID of the owner of the file, and the effective group ID of the process does not match the group ID of the file, and the appropriate access bit of the "other" portion (07) of the file mode is set.

Otherwise, the corresponding permissions are denied.

Message Queue Identifier A message queue identifier (msqid) is a unique positive integer created by a *msgget* (2) system call. Each msqid has a message queue and a data structure associated with it. The data structure is referred to as *msqid ds* and contains the following members:

```
ipc_perm msg_perm; /* operation permission struct */
struct
ushort
                              /* number of msgs on q */
        msg_qnum;
ushort
                              /* max number of bytes on q */
        msg_qbytes;
                              /* pid of last msgsnd operation */
ushort
        msg lspid;
ushort
        msg lrpid;
                              /* pid of last msgrcv operation */
time t
        msg stime;
                             /* last msgsnd time */
time t
        msg rtime;
                             /* last msgrcv time */
```

```
time_t msg_ctime; /* last change time */
/* Times measured in secs since */
/* 00:00:00 GMT, Jan. 1, 1970 */
```

Msg\_perm is an ipc\_perm structure that specifies the message operation permission (see below). This structure includes the following members:

```
ushort cuid; /* creator user id */
ushort cgid; /* creator group id */
ushort uid; /* user id */
ushort gid; /* group id */
ushort mode; /* r/w permission */
```

### msg qnum

is the number of messages currently on the queue.

### msg gbytes

is the maximum number of bytes allowed on the queue.

# msg\_lspid

is the process id of the last process that performed a msgsnd operation.

# msg\_lrpid

is the process id of the last process that performed a msgrcv operation.

#### msg stime

is the time of the last msgsnd operation.

#### msg rtime

is the time of the last msgrcv operation

#### msg ctime

is the time of the last msgctl(2) operation that changed a member of the above structure.

Message Operation Permissions In the *msgop*(2) and *msgctl*(2) system call descriptions, the permission required for an operation is given as "{token}", where "token" is the type of permission needed interpreted as follows:

00400	Read by user
00200	Write by user
00060	Read, Write by group
00006	Read. Write by others

Read and Write permissions on a msqid are granted to a process if one or more of the following are true:

The effective user ID of the process is super-user.

The effective user ID of the process matches msg\_perm.lcluid in the data structure associated with msqid and the appropriate bit of the "user" portion (0600) of msg\_perm.mode is set.

The effective user ID of the process does not match msg\_perm.lcluid and the effective group ID of the process matches msg\_perm.lclgid and the appropriate bit of the "group" portion (060) of msg\_perm.mode is set.

The effective user ID of the process does not match msg\_perm.lcluid and the effective group ID of the process does not match msg\_perm.lclgid and the appropriate bit of the "other" portion (06) of msg\_perm.mode is set.

Otherwise, the corresponding permissions are denied.

Semaphore Identifier A semaphore identifier (semid) is a unique positive integer created by a *semget* (2) system call. Each semid has a set of semaphores and a data structure associated with it. The data structure is referred to as *semid ds* and contains the following members:

```
struct ipc_perm sem_perm; /* operation permission struct */
ushort sem_nsems; /* number of sems in set */
time_t sem_otime; /* last operation time */
time_t sem_ctime; /* last change time */
/* Times measured in secs since */
/* 00:00:00 GMT, Jan. 1, 1970 */
```

Sem\_perm is an ipc\_perm structure that specifies the semaphore operation permission (see below). This structure includes the following members:

```
ushort cuid; /* creator user id */
ushort cgid; /* creator group id */
ushort uid; /* user id */
ushort gid; /* group id */
ushort mode; /* r/a permission */
```

The value of sem\_nsems is equal to the number of semaphores in the set. Each semaphore in the set is referenced by a positive integer referred to as a sem\_num. Sem\_num values run sequentially from 0 to the value of sem\_nsems minus 1. Sem\_otime is the time of the last semop(2) operation, and sem\_ctime is the time of the last semop(1) operation that changed a member of the above structure.

A semaphore is a data structure that contains the following members:

```
ushort semval; /* semaphore value */
short sempid; /* pid of last operation */
ushort semncnt; /* # awaiting semval > cval */
ushort semzcnt; /* # awaiting semval = 0 */
```

Semval is a non-negative integer. Sempid is equal to the process ID of the last process that performed a semaphore operation on this semaphore. Semnent is a count of the number of processes that are currently suspended awaiting this semaphore's semval to become greater than its current value. Semzent is a count of the number of processes that are currently suspended awaiting this semaphore's semval to become zero.

Semaphore Operation Permissions In the semop (2) and semctl (2) system call descriptions, the permission required for an operation is given as "{token}", where "token" is the type of permission needed interpreted as follows:

00400	Read by user
00200	Alter by user
00060	Read, Alter by group
00006	Read, Alter by others

Read and Alter permissions on a semid are granted to a process if one or more of the following are true:

The effective user ID of the process is super-user.

The effective user ID of the process matches sem\_perm.lcluid in the data structure associated with *semid* and the appropriate bit of the "user" portion (0600) of sem\_perm.mode is set.

The effective user ID of the process does not match sem perm.lcluid and the effective group ID of the process matches sem perm.lclgid and

the appropriate bit of the "group" portion (060) of sem\_perm.mode is set.

The effective user ID of the process does not match sem\_perm.lcluid and the effective group ID of the process does not match sem\_perm.lclgid and the appropriate bit of the "other" portion (06) of sem\_perm.mode is set.

Otherwise, the corresponding permissions are denied.

Shared Memory Identifier A shared memory identifier (shmid) is a unique positive integer created by a *shmget* (2) system call. Each shmid has a segment of memory (referred to as a shared memory segment) and a data structure associated with it. The data structure is referred to as *shmid\_ds* and contains the following members:

```
struct
        ipc perm shm perm; /* operation permission struct */
int
        shm segsz;
                               /* size of segment */
ushort
        shm cpid;
                               /* creator pid */
ushort
        shm lpid;
                               /* pid of last operation */
                              /* number of current attaches */
short
        shm nattch;
                              /* last attach time */
time t
        shm atime;
time t
        shm dtime;
                               /* last detach time */
                               /* last change time */
time t
        shm ctime;
                               /* Times measured in secs since */
                               /* 00:00:00 GMT, Jan. 1, 1970 */
```

Shm\_perm is an ipc\_perm structure that specifies the shared memory operation permission (see below). This structure includes the following members:

```
ushort cuid; /* creator user id */
ushort cgid; /* creator group id */
ushort uid; /* user id */
ushort gid; /* group id */
ushort mode; /* r/w permission */
```

Shm\_segsz specifies the size of the shared memory segment. Shm\_cpid is the process id of the process that created the shared memory identifier. Shm\_lpid is the process id of the last process that performed a shmop(2) operation. Shm\_nattch is the number of processes that currently have this segment attached. Shm\_atime is the time of the last shmat operation, shm\_dtime is the time of the last shmat operation, and shm\_ctime is the time of the last shmctl(2) operation that changed one of the members of the above structure.

Shared Memory Operation Permissions In the *shmop* (2) and *shmctl* (2) system call descriptions, the permission required for an operation is given as "{token}", where "token" is the type of permission needed interpreted as follows:

00400	Read by user
00200	Write by user
00060	Read, Write by group
00006	Read. Write by others

Read and Write permissions on a shmid are granted to a process if one or more of the following are true:

The effective user ID of the process is super-user.

The effective user ID of the process matches **shm\_perm.lcluid** in the data structure associated with *shmid* and the appropriate bit of the "user" portion (0600) of **shm perm.mode** is set.

The effective user ID of the process does not match **shm\_perm.lcluid** and the effective group ID of the process matches **shm\_perm.lclgid** and the appropriate bit of the "group" portion (060) of **shm\_perm.mode** is set.

The effective user ID of the process does not match shm\_perm.lcluid and the effective group ID of the process does not match shm\_perm.lclgid and the appropriate bit of the "other" portion (06) of shm perm.mode is set.

Otherwise, the corresponding permissions are denied.

SEE ALSO

close(2), ioctl(2), open(2), pipe(2), read(2), write(2), intro(3).

ACCESS(2) ACCESS(2)

### NAME

access - determine accessibility of a file

### SYNOPSIS

int access (path, amode) char \*path; int amode;

### DESCRIPTION

Path points to a path name naming a file. Access checks the named file for accessibility according to the bit pattern contained in amode, using the real user ID in place of the effective user ID and the real group ID in place of the effective group ID. The bit pattern contained in amode is constructed as follows:

04 read 02 write

01 execute (search) 00 check existence of file

Access to the file is denied if one or more of the following are true:

[ENOTDIR] A component of the path prefix is not a directory.

[ENOENT] Read, write, or execute (search) permission is

requested for a null path name.

[ENOENT] The named file does not exist.

[EACCES] Search permission is denied on a component of the

path prefix.

[EROFS] Write access is requested for a file on a read-only

file system.

[ETXTBSY] Write access is requested for a pure procedure

(shared text) file that is being executed.

[EACCESS] Permission bits of the file mode do not permit

the requested access.

[EFAULT] Path points outside the allocated address

space for the process.

The owner of a file has permission checked with respect to the "owner" read, write, and execute mode bits Members of the file's group other than the owner have permissions checked with respect to the "group" mode bits, and all others have permissions checked with respect to the "other" mode bits.

# SEE ALSO

chmod(2), stat(2).

### DIAGNOSTICS

If the requested access is permitted, a value of 0 is returned. Otherwise, a value of -1 is returned and *errno* is set to indicate the error.

ACCT(2) ACCT(2)

### NAME

acct - enable or disable process accounting

### **SYNOPSIS**

int acct (path) char \*path;

# DESCRIPTION

Acct is used to enable or disable the system process accounting routine. If the routine is enabled, an accounting record will be written on an accounting file for each process that terminates. Termination can be caused by one of two things: an exit call or a signal; see exit(2) and signal(2). The effective user ID of the calling process must be super-user to use this call.

Path points to a path name naming the accounting file. The accounting file format is given in acct (4).

The accounting routine is enabled if *path* is non-zero and no errors occur during the system call. It is disabled if *path* is zero and no errors occur during the system call.

Acct will fail if one or more of the following are true:

[EPERM] The effective user of the calling process is not super-user.

[EBUSY] An attempt is being made to enable accounting when it is

already enabled.

[ENOTDIR] A component of the path prefix is not a directory.

[ENOENT] One or more components of the accounting file path name do

not exist.

[EACCES] A component of the path prefix denies search permission.

[EACCES] The file named by path is not an ordinary file.

[EACCES] Mode permission is denied for the named accounting file.

[EISDIR] The named file is a directory.

[EROFS] The named file resides on a read-only file system.

[EFAULT] Path points to an illegal address.

### SEE ALSO

exit(2), signal(2), acct(4).

# DIAGNOSTICS

ALARM(2) ALARM(2)

# NAME

alarm - set a process alarm clock

# **SYNOPSIS**

unsigned alarm (sec) unsigned sec;

# DESCRIPTION

Alarm instructs the alarm clock of the calling process to send the signal SIGALRM to the calling process after the number of real time seconds specified by sec have elapsed; see signal (2).

Alarm requests are not stacked; successive calls reset the alarm clock of the calling process.

If sec is 0, any previously made alarm request is canceled.

# SEE ALSO

pause(2), signal(2).

# DIAGNOSTICS

Alarm returns the amount of time previously remaining in the alarm clock of the calling process.

BRK (2)

### NAME

brk, sbrk - change data segment space allocation

### **SYNOPSIS**

int brk (endds) char \*endds; char \*sbrk (incr) int incr;

### DESCRIPTION

Brk and sbrk are used to change dynamically the amount of space allocated for the calling process's data segment; see exec(2). The change is made by resetting the process's break value and allocating the appropriate amount of space. The break value is the address of the first location beyond the end of the data segment. The amount of allocated space increases as the break value increases. The newly allocated space is set to zero.

Brk sets the break value to endds and changes the allocated space accordingly.

Sbrk adds incr bytes to the break value and changes the allocated space accordingly. Incr can be negative, in which case the amount of allocated space is decreased.

Brk and sbrk will fail without making any change in the allocated space if one or more of the following are true:

[ENOMEM] Using brk(0) or brk(.textaddress).

[ENOMEM] Such a change would result in more space being allocated than is allowed by a system-imposed maximum (see *ulimit*(2)).

Such a change would result in the break value being greater than or equal to the start address of any attached shared memory segment (see shmop(2)).

# SEE ALSO

exec(2), shmop(2), ulimit(2).

### DIAGNOSTICS

Upon successful completion, brk returns a value of 0 and sbrk returns the old break value. Otherwise, a value of -1 is returned and errno is set to indicate the error.

CHDIR (2) CHDIR (2)

NAME

chdir - change working directory

**SYNOPSIS** 

int chdir (path) char \*path;

### DESCRIPTION

Path points to the path name of a directory. Chdir causes the named directory to become the current working directory, the starting point for path searches for path names not beginning with /.

Chdir will fail and the current working directory will be unchanged if one or more of the following are true:

[ENOTDIR] A component of the path name is not a directory.

[ENOENT] The named directory does not exist.

[EACCES] Search permission is denied for any component of the path

name.

[EFAULT] Path points outside the allocated address space of the process.

SEE ALSO

chroot(2).

# DIAGNOSTICS

CHMOD(2) CHMOD(2)

#### NAME

chmod - change mode of file

# **SYNOPSIS**

int chmod (path, mode) char \*path; int mode;

#### DESCRIPTION

Path points to a path name naming a file. Chmod sets the access permission portion of the named file's mode according to the bit pattern contained in mode.

Access permission bits are interpreted as follows:

04000	Set user ID on execution.
02000	Set group ID on execution.
01000	Save text image after execution.
00400	Read by owner.
00200	Write by owner.
00100	Execute (search if a directory) by owner.
00070	Read, write, execute (search) by group.
00007	Read, write, execute (search) by others.

The effective user ID of the process must match the owner of the file or be super-user to change the mode of a file.

If the effective user ID of the process is not super-user, mode bit 01000 (save text image on execution) is cleared.

If the effective user ID of the process is not super-user and the effective group ID of the process does not match the group ID of the file, mode bit 02000 (set group ID on execution) is cleared.

If an executable file is prepared for sharing then mode bit 01000 prevents the system from abandoning the swap-space image of the program-text portion of the file when its last user terminates. Thus, when the next user of the file executes it, the text need not be read from the file system but can simply be swapped in, saving time.

Chmod will fail and the file mode will be unchanged if one or more of the following are true:

[ENOTDIR]	A component of the path prefix is not a directory.

[	771 1 01 1	
[ENOENT]	The named file does not exist.	

[EACCES] Search permission is denied on a component of the path

prefix.

[EPERM] The effective user ID does not match the owner of the file and

the effective user ID is not super-user.

[EROFS] The named file resides on a read-only file system.

[EFAULT] Path points outside the allocated address space of the process.

### **SEE ALSO**

chown(2), mknod(2).

# DIAGNOSTICS

CHOWN(2) CHOWN(2)

### NAME

chown - change owner and group of a file

### **SYNOPSIS**

int chown (path, owner, group) char \*path; int owner, group;

#### DESCRIPTION

Path points to a path name naming a file. The owner ID and group ID of the named file are set to the numeric values contained in owner and group respectively.

Only processes with effective user ID equal to the file owner or super-user may change the ownership of a file.

If *chown* is invoked by other than the super-user, the set-user-ID and set-group-ID bits of the file mode, 04000 and 02000 respectively, will be cleared.

Chown will fail and the owner and group of the named file will remain unchanged if one or more of the following are true:

[ENOTDIR] A component of the path prefix is not a directory.

[ENOENT] The named file does not exist.

[EACCES] Search permission is denied on a component of the path

prefix.

[EPERM] The effective user ID does not match the owner of the file and

the effective user ID is not super-user.

[EROFS] The named file resides on a read-only file system.

[EFAULT] Path points outside the allocated address space of the process.

#### SEE ALSO

chmod(2).

chown(1) in the 3B2 Computer System User Reference Manual.

# DIAGNOSTICS

CHROOT(2) CHROOT(2)

NAME

chroot - change root directory

# **SYNOPSIS**

int chroot (path) char \*path;

# DESCRIPTION

Path points to a path name naming a directory. Chroot causes the named directory to become the root directory, the starting point for path searches for path names beginning with /. The user's working directory is unaffected by the chroot system call.

The effective user ID of the process must be super-user to change the root directory.

The .. entry in the root directory is interpreted to mean the root directory itself. Thus, .. cannot be used to access files outside the subtree rooted at the root directory.

Chroot will fail and the root directory will remain unchanged if one or more of the following are true:

[ENOTDIR]

Any component of the path name is not a directory.

[ENOENT]

The named directory does not exist.

[EPERM]

The effective user ID is not super-user.

[EFAULT]

Path points outside the allocated address space of the process.

### **SEE ALSO**

chdir(2).

# DIAGNOSTICS

CLOSE(2) CLOSE(2)

# NAME

close - close a file descriptor

### **SYNOPSIS**

int close (fildes) int fildes;

# DESCRIPTION

Fildes is a file descriptor obtained from a creat, open, dup, fcntl, or pipe system call. Close closes the file descriptor indicated by fildes. All outstanding record locks owned by the process (on the file indicated by fildes) are removed.

Close will fail if fildes is not a valid open file descriptor.

# **SEE ALSO**

creat(2), dup(2), exec(2), fcntl(2), open(2), pipe(2).

# DIAGNOSTICS

CREAT(2) CREAT(2)

NAME

creat - create a new file or rewrite an existing one

### **SYNOPSIS**

int creat (path, mode) char \*path; int mode;

#### DESCRIPTION

Creat creates a new ordinary file or prepares to rewrite an existing file named by the path name pointed to by path.

If the file exists, the length is truncated to 0 and the mode and owner are unchanged. Otherwise, the file's owner ID is set to the effective user ID, of the process the group ID of the process is set to the effective group ID, of the process and the low-order 12 bits of the file mode are set to the value of *mode* modified as follows:

All bits set in the process's file mode creation mask are cleared. See *umask* (2).

The "save text image after execution bit" of the mode is cleared. See *chmod* (2).

Upon successful completion, the file descriptor is returned and the file is open for writing, even if the mode does not permit writing. The file pointer is set to the beginning of the file. The file descriptor is set to remain open across exec system calls. See fcntl(2). No process may have more than 20 files open simultaneously. A new file may be created with a mode that forbids writing.

Creat will fail if one or more of the following are true:

[ENOTDIR] A c	component of	the path	prefix is	not a	directory.
---------------	--------------	----------	-----------	-------	------------

[ENOENT] A component of the path prefix does not exist.

[EACCES] Search permission is denied on a component of the path

prefix.

[ENOENT] The path name is null.

[EACCES] The file does not exist and the directory in which the file is to

be created does not permit writing.

[EROFS] The named file resides or would reside on a read-only file sys-

tem.

[ETXTBSY] The file is a pure procedure (shared text) file that is being

executed.

[EACCES] The file exists and write permission is denied.

[EISDIR] The named file is an existing directory.

[EMFILE] Twenty (20) file descriptors are currently open.

[EFAULT] Path points outside the allocated address space of the process.

[ENFILE] The system file table is full.

# SEE ALSO

chmod(2), close(2), dup(2), fcntl(2), lseek(2), open(2), read(2), umask(2), write(2).

### DIAGNOSTICS

Upon successful completion, a non-negative integer, namely the file descriptor, is returned. Otherwise, a value of -1 is returned and *errno* is set to indicate the error.

DUP(2)

### NAME

dup - duplicate an open file descriptor

# **SYNOPSIS**

int dup (fildes) int fildes;

# DESCRIPTION

Fildes is a file descriptor obtained from a creat, open, dup, fcntl, or pipe system call. Dup returns a new file descriptor having the following in common with the original:

Same open file (or pipe).

Same file pointer (i.e., both file descriptors share one file pointer).

Same access mode (read, write or read/write).

The new file descriptor is set to remain open across exec system calls. See fcntl(2).

The file descriptor returned is the lowest one available.

Dup will fail if one or more of the following are true:

[EBADF]

Fildes is not a valid open file descriptor.

[EMFILE]

Twenty (20) file descriptors are currently open.

# **SEE ALSO**

creat(2), close(2), exec(2), fcntl(2), open(2), pipe(2).

# DIAGNOSTICS

Upon successful completion a non-negative integer, namely the file descriptor, is returned. Otherwise, a value of -1 is returned and *errno* is set to indicate the error.

EXEC(2) EXEC(2)

### NAME

execl, execv, execle, execve, execlp, execvp - execute a file

### **SYNOPSIS**

```
int execl (path, arg0, arg1, ..., argn, 0)
char *path, *arg0, *arg1, ..., *argn;
int execv (path, argv)
char *path, *argv[ ];
int execle (path, arg0, arg1, ..., argn, 0, envp)
char *path, *arg0, *arg1, ..., *argn, *envp[ ];
int execve (path, argv, envp)
char *path, *argv[ ], *envp[ ];
int execlp (file, arg0, arg1, ..., argn, 0)
char *file, *arg0, *arg1, ..., *argn;
int execvp (file, argv)
char *file, *argv[ ];
```

#### DESCRIPTION

Exec in all its forms transforms the calling process into a new process. The new process is constructed from an ordinary, executable file called the new process file. This file consists of a header (see a.out(4)), a text segment, and a data segment. The data segment contains an initialized portion and an uninitialized portion (bss). There can be no return from a successful exec because the calling process is overlaid by the new process.

When a C program is executed, it is called as follows:

```
main (argc, argv, envp)
int argc;
char **argv, **envp;
```

where argc is the argument count and argv is an array of character pointers to the arguments themselves. As indicated, argc is conventionally at least one and the first member of the array points to a string containing the name of the file.

Path points to a path name that identifies the new process file.

File points to the new process file. The path prefix for this file is obtained by a search of the directories passed as the *environment* line "PATH =" (see *environ*(5)). The environment is supplied by the shell (see sh(1)).

Arg0, arg1, ..., argn are pointers to null-terminated character strings. These strings constitute the argument list available to the new process. By convention, at least arg0 must be present and point to a string that is the same as path (or its last component).

Argv is an array of character pointers to null-terminated strings. These strings constitute the argument list available to the new process. By convention, argv must have at least one member, and it must point to a string that is the same as path (or its last component). Argv is terminated by a null pointer.

Envp is an array of character pointers to null-terminated strings. These strings constitute the environment for the new process. Envp is terminated by a null pointer. For execl and execv, the C run-time start-off routine places a pointer to the environment of the calling process in the global cell:

# extern char \*\*environ;

and it is used to pass the environment of the calling process to the new process.

File descriptors open in the calling process remain open in the new process, except for those whose close-on-exec flag is set; see *fcntl*(2). For those file descriptors that remain open, the file pointer is unchanged.

10/84 - 1 - 10/84

EXEC(2) EXEC(2)

Signals set to terminate the calling process will be set to terminate the new process. Signals set to be ignored by the calling process will be set to be ignored by the new process. Signals set to be caught by the calling process will be set to terminate new process; see *signal(2)*.

If the set-user-ID mode bit of the new process file is set (see *chmod*(2)), *exec* sets the effective user ID of the new process to the owner ID of the new process file. Similarly, if the set-group-ID mode bit of the new process file is set, the effective group ID of the new process is set to the group ID of the new process file. The real user ID and real group ID of the new process remain the same as those of the calling process.

The shared memory segments attached to the calling process will not be attached to the new process (see *shmop*(2)).

Profiling is disabled for the new process; see profil(2).

The new process also inherits the following attributes from the calling process:

nice value (see nice(2))
process ID
parent process ID
process group ID
semadj values (see semop(2))
tty group ID (see exit(2) and signal(2))
trace flag (see ptrace(2) request 0)
time left until an alarm clock signal (see alarm(2))
current working directory
root directory
file mode creation mask (see umask(2))
file size limit (see ulimit(2))
utime, stime, cutime, and cstime (see times(2))

Exec will fail and return to the calling process if one or more of the following are true:

[ENOENT]	One or more components of the new process path name of the file do not exist.
[ENOTDIR]	A component of the new process path of the file prefix is not a directory.
[EACCES]	Search permission is denied for a directory listed in the new process file's path prefix.
[EACCES]	The new process file is not an ordinary file.
[EACCES]	The new process file mode denies execution permission.
[ENOEXEC]	The exec is not an execlp or execvp, and the new process file

has the appropriate access permission but an invalid magic number in its header.

[ETXTBSY] The new process file is a pure procedure (shared text) file that is currently open for writing by some process.

[ENOMEM] The new process requires more memory than is allowed by the system-imposed maximum MAXMEM.

The number of bytes in the new process's argument list is greater than the system-imposed limit of 5120 bytes.

[EFAULT] The new process file is not as long as indicated by the size

values in its header.

[EFAULT] Path, argv, or envp point to an illegal address.

[E2BIG]

EXEC(2)

# SEE ALSO

alarm(2), exit(2), fork(2), nice(2), ptrace(2), semop(2), signal(2), times(2), ulimit(2), umask(2), a.out(4), environ(5). sh(1) in the 3B2 Computer System User Reference Manual.

# DIAGNOSTICS

If exec returns to the calling process an error has occurred; the return value will be -1 and errno will be set to indicate the error.

EXIT(2) EXIT(2)

```
NAME
```

exit, exit - terminate process

### SYNOPSIS

void exit (status) int status: void exit (status) int status;

### DESCRIPTION

Exit terminates the calling process with the following consequences:

All of the file descriptors open in the calling process are closed.

If the parent process of the calling process is executing a wait, it is notified of the calling process's termination and the low order eight bits (i.e., bits 0377) of status are made available to it; see wait (2).

If the parent process of the calling process is not executing a wait, the calling process is transformed into a zombie process. A zombie process is a process that only occupies a slot in the process table. It has no other space allocated either in user or kernel space. The process table slot that it occupies is partially overlaid with time accounting information (see <sys/proc.h>) to be used by times.

The parent process ID of all of the calling process's existing child processes and zombie processes is set to 1. This means the initialization process (see intro(2)) inherits each of these processes.

Each attached shared memory segment is detached and the value of shm\_nattach in the data structure associated with its shared memory identifier is decremented by 1.

For each semaphore for which the calling process has set a semadj value (see semop (2)), that semadj value is added to the semval of the specified semaphore.

If the process has a process, text, or data lock, an unlock is performed (see plock(2)).

An accounting record is written on the accounting file if the system's accounting routine is enabled; see acct (2).

If the process ID, tty group ID, and process group ID of the calling process are equal, the SIGHUP signal is sent to each process that has a process group ID equal to that of the calling process.

The C function exit may cause cleanup actions before the process exits. The function exit circumvents all cleanup.

### WARNING

See WARNING in signal (2).

FCNTL(2) FCNTL(2)

NAME

fcntl - file control

SYNOPSIS

#include <fcntl.h>

int fcntl (fildes, cmd, arg) int fildes, cmd, arg;

### DESCRIPTION

Fcntl provides for control over open files. Fildes is an open file descriptor obtained from a creat, open, dup, fcntl, or pipe system call.

The commands available are:

F DUPFD

Return a new file descriptor as follows:

Lowest numbered available file descriptor greater than or equal to arg.

Same open file (or pipe) as the original file.

Same file pointer as the original file (i.e., both file descriptors share one file pointer).

Same access mode (read, write or read/write).

Same file status flags (i.e., both file descriptors share the same file status flags).

The close-on-exec flag associated with the new file descriptor is set to remain open across exec(2) system calls.

F GETFD

Get the close-on-exec flag associated with the file descriptor fildes. If the low-order bit is 0 the file will remain open across exec, otherwise the file will be closed upon execution of exec.

F\_SETFD

Set the close-on-exec flag associated with fildes to the loworder bit of arg (0 or 1 as above).

F GETFL

Get file status flags.

F SETFL

Set file status flags to arg. Only certain flags can be set; see fcntl(5).

F GETLK

Get the first lock which blocks the lock description given by the variable of type *struct flock* pointed to by *arg*. The information retrieved overwrites the information passed to *fcntl* in the *flock* structure. If no lock is found that would prevent this lock from being created, then the structure is passed back unchanged except for the lock type which will be set to F UNLCK.

F SETLK

Set or clear a file segment lock according to the variable of type struct flock pointed to by arg (see fcntl(5)). The cmd  $F\_SETLK$  is used to establish read ( $F\_RDLCK$ ) and write ( $F\_WRLCK$ ) locks, as well as remove either type of lock ( $F\_UNLCK$ ). If a read or write lock cannot be set fcntl will return immediately with an error value of -1.

F SETLKW

This *cmd* is the same as F\_SETLK except that if a read or write lock is blocked by other locks, the process will sleep until the segment is free to be locked.

A read lock prevents any process from write locking the protected area. More than one read lock may exist for a given segment of a file at a given time. The file descriptor on which a read lock is being placed must have been opened with

FCNTL(2) FCNTL(2)

read access.

A write lock prevents any process from read locking or write locking the protected area. Only one write lock may exist for a given segment of a file at a given time. The file descriptor on which a write lock is being placed must have been opened with write access.

The structure *flock* describes the type (*l\_type*), starting offset (*l\_whence*), relative offset (*l\_start*), size (*l\_len*), and process id (*l\_pid*) of the segment of the file to be affected. The process id field is only used with the F\_GETLK *cmd* to return the value for a blocking lock. Locks may start and extend beyond the current end of a file, but may not be negative relative to the beginning of the file. A lock may be set to always extend to the end of file by setting *l\_len* to zero (0). If such a lock also has *l\_start* set to zero (0), the whole file will be locked. Changing or unlocking a segment from the middle of a larger locked segment leaves two smaller segments for either end. Locking a segment that is already locked by the calling process causes the old lock type to be removed and the new lock type to take affect. All locks associated with a file for a given process are removed when a file descriptor for that file is closed by that process or the process holding that file descriptor terminates. Locks are not inherited by a child process in a *fork*(2) system call.

Fcntl will fail if one or more of the following are true:

[EBADF] Fildes is not a valid open file descriptor.

[EMFILE] Cmd is F\_DUPFD and 20 file descriptors are currently open.

[EINFILE] Cmd is F\_DUPFD and arg is negative or greater than 20.

[EINVAL] Cmd is F\_GETLK, F\_SETLK, or SETLKW and arg or the data

it points to is not valid.

[EACCESS] Cmd is F\_SETLK the type of lock (l\_type) is a read

(F\_RDLCK) or write (F\_WRLCK lock and the segment of a file to be locked is already write locked by another process or the type is a write lock and the segment of a file to be locked

is already read or write locked by another process.

[EMFILE] Cmd is F SETLK or F SETLKW, the type of lock is a read or

write lock and there are no more file locking headers available

(too many files have segments locked).

[ENOSPC] Cmd is F\_SETLK or F\_SETLKW, the type of lock is a read or

write lock and there are no more file locking headers available (too many files have segments locked) or there are no more

record locks available (too many file segments locked).

[EDEADLK] Cmd is F SETLKW, the lock is blocked by some lock from

another process and sleeping (waiting) for that lock to become

free. This would cause a deadlock situation.

## SEE ALSO

close(2), exec(2), open(2), fcntl(5).

### DIAGNOSTICS

Upon successful completion, the value returned depends on cmd as follows:

F DUPFD A new file descriptor.

F GETFD Value of flag (only the low-order bit is defined).

F SETFD Value other than -1.
F GETFL Value of file flags.
F SETFL Value other than -1.

FCNTL(2) FCNTL(2)

F\_GETLK Value other than -1.
F\_SETLK Value other than -1.
F\_SETLKW Value other than -1.
Otherwise, a value of -1 is returned and errno is set to indicate the error.

FORK(2) FORK(2)

```
NAME
```

fork - create a new process

#### SYNOPSIS

int fork ()

#### DESCRIPTION

Fork causes creation of a new process. The new process (child process) is an exact copy of the calling process (parent process). This means the child process inherits the following attributes from the parent process:

environment close-on-exec flag (see exec(2)) signal handling settings (i.e., SIG DFL, SIG IGN, function address) set-user-ID mode bit set-group-ID mode bit profiling on/off status nice value (see nice (2)) all attached shared memory segments (see shmop (2)) process group ID tty group ID (see exit(2) and signal(2)) trace flag (see ptrace (2) request 0) time left until an alarm clock signal (see alarm (2)) current working directory root directory file mode creation mask (see umask (2)) file size limit (see *ulimit* (2))

The child process differs from the parent process in the following ways:

The child process has a unique process ID.

The child process has a different parent process ID (i.e., the process ID of the parent process).

The child process has its own copy of the parent's file descriptors. Each of the child's file descriptors shares a common file pointer with the corresponding file descriptor of the parent.

All semadj values are cleared (see semop (2)).

Process locks, text locks and data locks are not inherited by the child (see *plock* (2)).

The child process's utime, stime, cutime, and cstime are set to 0. The time left until an alarm clock signal is reset to 0.

Fork will fail and no child process will be created if one or more of the following are true:

[EAGAIN] The system-imposed limit on the total number of processes under execution would be exceeded.

[EAGAIN] The system-imposed limit on the total number of processes under execution by a single user would be exceeded.

FORK(2) FORK(2)

# **SEE ALSO**

exec(2), nice(2), plock(2), ptrace(2), semop(2), shmop(2), signal(2), times(2), ulimit(2), umask(2), wait(2).

# DIAGNOSTICS

Upon successful completion, fork returns a value of 0 to the child process and returns the process ID of the child process to the parent process. Otherwise, a value of -1 is returned to the parent process, no child process is created, and errno is set to indicate the error.

IOCTL(2)

NAME

ioctl - control device

SYNOPSIS

ioctl (fildes, request, arg) int fildes, request;

### DESCRIPTION

Ioctl performs a variety of functions on character special files (devices). The write-ups of various devices in Section 7 of the 3B2 Computer System Administration Utilities Guide discuss how ioctl applies to them.

Ioctl will fail if one or more of the following are true:

[EBADF] Fildes is not a valid open file descriptor.

[ENOTTY] Fildes is not associated with a character special device.

[EINVAL] Request or arg is not valid. See Section 7 of the UNIX Sys-

tem V Administrator Reference Manual.

[EINTR] A signal was caught during the ioctl system call.

SEE ALSO

termio(7) in the 3B2 Computer System Administration Utilities Guide.

DIAGNOSTICS

If an error has occurred, a value of -1 is returned and *errno* is set to indicate the error.

KILL(2) KILL(2)

NAME

kill - send a signal to a process or a group of processes

### **SYNOPSIS**

int kill (pid, sig) int pid, sig;

### DESCRIPTION

Kill sends a signal to a process or a group of processes. The process or group of processes to which the signal is to be sent is specified by pid. The signal that is to be sent is specified by sig and is either one from the list given in signal(2), or 0. If sig is 0 (the null signal), error checking is performed but no signal is actually sent. This can be used to check the validity of pid.

The real or effective user ID of the sending process must match the real or effective user ID of the receiving process, unless the effective user ID of the sending process is super-user.

The processes with a process ID of 0 and a process ID of 1 are special processes (see *intro*(2)) and will be referred to below as *proc0* and *proc1*, respectively.

If *pid* is greater than zero, *sig* will be sent to the process whose process ID is equal to *pid*. *Pid* may equal 1.

If *pid* is 0, *sig* will be sent to all processes excluding *proc0* and *proc1* whose process group ID is equal to the process group ID of the sender.

If pid is -1 and the effective user ID of the sender is not super-user, sig will be sent to all processes excluding proc0 and proc1 whose real user ID is equal to the effective user ID of the sender.

If pid is -1 and the effective user ID of the sender is super-user, sig will be sent to all processes excluding proc0 and proc1.

If pid is negative but not -1, sig will be sent to all processes whose process group ID is equal to the absolute value of pid.

Kill will fail and no signal will be sent if one or more of the following are true:

[EINVAL] Sig is not a valid signal number.

[EINVAL] Sig is SIGKILL and pid is 1 (proc1).

[ESRCH] No process can be found corresponding to that specified by

pid.

[EPERM] The user ID of the sending process is not super-user, and its

real or effective user ID does not match the real or effective

user ID of the receiving process.

# SEE ALSO

getpid(2), setpgrp(2), signal(2).

kill(1) in the 3B2 Computer System User Reference Manual.

# DIAGNOSTICS

LINK(2) LINK(2)

NAME

link - link to a file

# **SYNOPSIS**

int link (path1, path2) char \*path1, \*path2;

### DESCRIPTION

Path1 points to a path name naming an existing file. Path2 points to a path name naming the new directory entry to be created. Link creates a new link (directory entry) for the existing file.

Link will fail and no link will be created if one or more of the following are true:

A component of either path prefix is not a directory. [ENOTDIR]

A component of either path prefix does not exist. [ENOENT]

A component of either path prefix denies search permission. [EACCES]

The file named by path1 does not exist. [ENOENT]

The link named by path2 exists. [EEXIST]

The file named by path1 is a directory and the effective user [EPERM]

ID is not super-user.

The link named by path2 and the file named by path1 are on [EXDEV]

different logical devices (file systems).

Path2 points to a null path name. [ENOENT]

The requested link requires writing in a directory with a mode [EACCES]

that denies write permission.

The requested link requires writing in a directory on a read-[EROFS]

only file system.

Path points outside the allocated address space of the process. [EFAULT]

The maximum number of links to a file would be exceeded. [EMLINK]

SEE ALSO

unlink(2).

### DIAGNOSTICS

LSEEK (2) LSEEK (2)

NAME

lseek - move read/write file pointer

# **SYNOPSIS**

long lseek (fildes, offset, whence) int fildes; long offset; int whence;

### DESCRIPTION

Fildes is a file descriptor returned from a creat, open, dup, or fcntl system call. Lseek sets the file pointer associated with fildes as follows:

If whence is 0, the pointer is set to offset bytes.

If whence is 1, the pointer is set to its current location plus offset.

If whence is 2, the pointer is set to the size of the file plus offset.

Upon successful completion, the resulting pointer location, as measured in bytes from the beginning of the file, is returned.

Lseek will fail and the file pointer will remain unchanged if one or more of the following are true:

[EBADF]

Fildes is not an open file descriptor.

[ESPIPE]

Fildes is associated with a pipe or fifo.

[EINVAL and SIGSYS signal]

Whence is not 0, 1, or 2.

[EINVAL]

The resulting file pointer would be negative.

Some devices are incapable of seeking. The value of the file pointer associated with such a device is undefined.

#### SEE ALSO

creat(2), dup(2), fcntl(2), open(2).

# DIAGNOSTICS

Upon successful completion, a non-negative integer indicating the file pointer value is returned. Otherwise, a value of -1 is returned and *errno* is set to indicate the error.

MKNOD(2) MKNOD(2)

### NAME

mknod - make a directory, or a special or ordinary file

### **SYNOPSIS**

int mknod (path, mode, dev) char \*path; int mode, dev;

### DESCRIPTION

Mknod creates a new file named by the path name pointed to by path. The mode of the new file is initialized from mode. Where the value of mode is interpreted as follows:

0170000 file type; one of the following:

0010000 fifo special 0020000 character special 0040000 directory 0060000 block special

0100000 or 0000000 ordinary file

0004000 set user ID on execution 0002000 set group ID on execution 0001000 save text image after execution

0000777 access permissions; constructed from the following 0000400 read by owner

0000200 write by owner 0000100 execute (search on directory) by owner 0000070 read, write, execute (search) by group 0000007 read, write, execute (search) by others

The owner ID of the file is set to the effective user ID of the process. The group ID of the file is set to the effective group ID of the process.

Values of *mode* other than those above are undefined and should not be used. The low-order 9 bits of *mode* are modified by the process's file mode creation mask: all bits set in the process's file mode creation mask are cleared. See *umask*(2). If *mode* indicates a block or character special file, *dev* is a configuration-dependent specification of a character or block I/O device. If *mode* does not indicate a block special or character special device, *dev* is ignored.

Mknod may be invoked only by the super-user for file types other than FIFO special.

Mknod will fail and the new file will not be created if one or more of the following are true:

[EPERM] The effective user ID of the process is not super-user.

[ENOTDIR] A component of the path prefix is not a directory.

[ENOENT] A component of the path prefix does not exist.

[EROFS] The directory in which the file is to be created is located on a

read-only file system.

[EEXIST] The named file exists.

[EFAULT] Path points outside the allocated address space of the process.

MKNOD(2) MKNOD(2)

# SEE ALSO

chmod(2), exec(2), umask(2), fs(4).
mkdir(1) in the 3B2 Computer System User Reference Manual.

#### DIAGNOSTICS

MOUNT(2) MOUNT(2)

### NAME

mount - mount a file system

### **SYNOPSIS**

int mount (spec, dir, rwflag)
char \*spec, \*dir;
int rwflag;

### DESCRIPTION

Mount requests that a removable file system contained on the block special file identified by spec be mounted on the directory identified by dir. Spec and dir are pointers to path names.

Upon successful completion, references to the file dir will refer to the root directory on the mounted file system.

The low-order bit of *rwflag* is used to control write permission on the mounted file system; if 1, writing is forbidden, otherwise writing is permitted according to individual file accessibility.

Mount may be invoked only by the super-user.

Mount will fail if one or more of the following are true:

[EPERM] The effective user ID is not super-user.

[ENOENT] Any of the named files does not exist.

[ENOTDIR] A component of a path prefix is not a directory.

[ENOTBLK] Spec is not a block special device.

[ENXIO] The device associated with spec does not exist.

[ENOTDIR] Dir is not a directory.

[EFAULT] Spec or dir points outside the allocated address space of the

process.

[EBUSY] Dir is currently mounted on, is someone's current working

directory, or is otherwise busy.

[EBUSY] The device associated with *spec* is currently mounted.

[EBUSY] There are no more mount table entries.

[EROFS] Spec is write protected and rwflag requests write permission.

[ENOSPC] The file system state in the super-block is not FsOKAY and

rwflag requests write permission.

[EINVAL] The file system magic is not FsMAGIC.

# SEE ALSO

umount(2), fs(4).

# DIAGNOSTICS

MSGCTL(2) MSGCTL(2)

#### NAME

msgctl - message control operations

#### **SYNOPSIS**

#include <sys/types.h>
#include <sys/ipc.h>
#include <sys/msg.h>
int msgctl (msqid, cmd, buf)
int msqid, cmd;
struct msqid ds \*buf;

### DESCRIPTION

Msgctl provides a variety of message control operations as specified by cmd. The following cmds are available:

IPC STAT

Place the current value of each member of the data structure associated with *msqid* into the structure pointed to by *buf*. The contents of this structure are defined in *intro*(2). {READ}

IPC SET

Set the value of the following members of the data structure associated with *msqid* to the corresponding value found in the structure pointed to by *buf*:

msg\_perm.uid msg\_perm.gid msg\_perm.mode /\* only low 9 bits \*/ msg\_qbytes

This *cmd* can only be executed by a process that has an effective user ID equal to either that of super user or to the value of **msg\_perm.uid** in the data structure associated with *msqid*. Only super user can raise the value of **msg\_qbytes**.

IPC RMID

Remove the message queue identifier specified by *msqid* from the system and destroy the message queue and data structure associated with it. This *cmd* can only be executed by a process that has an effective user ID equal to either that of super user or to the value of **msg\_perm.uid** in the data structure associated with *msqid*.

Msgctl will fail if one or more of the following are true:

[EINVAL]

Msqid is not a valid message queue identifier.

[EINVAL]

Cmd is not a valid command.

[EACCES]

Cmd is equal to IPC\_STAT and {READ} operation permission

is denied to the calling process (see intro(2)).

[EPERM]

Cmd is equal to IPC\_RMID or IPC\_SET. The effective user ID of the calling process is not equal to that of super user and it is not equal to the value of msg\_perm.uid in the data structure associated with msqid.

[EPERM]

Cmd is equal to IPC\_SET, an attempt is being made to increase to the value of msg\_qbytes, and the effective user ID of the calling process is not equal to that of super user.

[EFAULT]

Buf points to an illegal address.

#### SEE ALSO

intro(2), msgget(2), msgop(2).

# DIAGNOSTICS

MSGGET (2) MSGGET (2)

### NAME

msgget - get message queue

### **SYNOPSIS**

#include <sys/types.h> #include <sys/ipc.h> #include <sys/msg.h> int msgget (key, msgflg) key\_t key; int msgflg;

# DESCRIPTION

Msgget returns the message queue identifier associated with key.

A message queue identifier and associated message queue and data structure (see *intro*(2)) are created for *key* if one of the following are true:

10 Key is equal to IPC\_PRIVATE.

Key does not already have a message queue identifier associated with it, and (msgflg & IPC\_CREAT) is "true".

Upon creation, the data structure associated with the new message queue identifier is initialized as follows:

Msg\_perm.cuid, msg\_perm.uid, msg\_perm.cgid, and msg\_perm.gid are set equal to the effective user ID and effective group ID, respectively, of the calling process.

The low-order 9 bits of msg\_perm.mode are set equal to the low-order 9 bits of msgflg.

Msg\_qnum, msg\_lspid, msg\_lrpid, msg\_stime, and msg\_rtime are set equal to 0.

Msg ctime is set equal to the current time.

Msg qbytes is set equal to the system limit.

Msgget will fail if one or more of the following are true:

[EACCES] A message queue identifier exists for key, but operation per-

mission (see intro(2)) as specified by the low-order 9 bits of

msgflg would not be granted.

[ENOENT] A message queue identifier does not exist for key and (msgflg

& IPC CREAT) is "false".

[ENOSPC] A message queue identifier is to be created but the system-

imposed limit on the maximum number of allowed message

queue identifiers system wide would be exceeded.

[EEXIST] A message queue identifier exists for key but ( (msgflg &

IPC CREAT) & ( msgflg & IPC\_EXCL) ) is "true".

### SEE ALSO

intro(2), msgctl(2), msgop(2).

### DIAGNOSTICS

Upon successful completion, a non-negative integer, namely a message queue identifier, is returned. Otherwise, a value of -1 is returned and *errno* is set to indicate the error.

MSGOP(2) MSGOP(2)

#### NAME

msgop - message operations

### **SYNOPSIS**

```
#include <sys/types.h>
#include <sys/ipc.h>
#include <sys/msg.h>
int msgsnd (msqid, msgp, msgsz, msgflg)
int msqid;
struct msgbuf *msgp;
int msgsz, msgflg;
int msgrcv (msqid, msgp, msgsz, msgtyp, msgflg)
int msqid;
struct msgbuf *msgp;
int msgsz;
long msgtyp;
int msgflg;
```

#### DESCRIPTION

Msgsnd is used to send a message to the queue associated with the message queue identifier specified by *msqid*. {WRITE} *Msgp* points to a structure containing the message. This structure is composed of the following members:

```
long mtype; /* message type */
char mtext[]; /* message text */
```

Mtype is a positive integer that can be used by the receiving process for message selection (see msgrcv below). Mtext is any text of length msgsz bytes. Msgsz can range from 0 to a system-imposed maximum.

Msgflg specifies the action to be taken if one or more of the following are true:

The number of bytes already on the queue is equal to msg\_qbytes (see intro(2)).

The total number of messages on all queues system-wide is equal to the system-imposed limit.

These actions are as follows:

If (msgflg & IPC\_NOWAIT) is "true", the message will not be sent and the calling process will return immediately.

If (msgflg & IPC\_NOWAIT) is "false", the calling process will suspend execution until one of the following occurs:

The condition responsible for the suspension no longer exists, in which case the message is sent.

Msqid is removed from the system (see msgctl(2)). When this occurs, errno is set equal to EIDRM, and a value of -1 is returned

The calling process receives a signal that is to be caught. In this case the message is not sent and the calling process resumes execution in the manner prescribed in *signal*(2)).

Msgsnd will fail and no message will be sent if one or more of the following are true:

[EINVAL] Msqid is not a valid message queue identifier.

[EACCES] Operation permission is denied to the calling process (see intro (2)).

MSGOP(2) MSGOP(2)

[EINVAL] Mtype is less than 1.

[EAGAIN] The message cannot be sent for one of the reasons cited above

and (msgflg & IPC\_NOWAIT) is "true".

[EINVAL] Msgsz is less than zero or greater than the system-imposed

imit.

[EFAULT] Msgp points to an illegal address.

Upon successful completion, the following actions are taken with respect to the data structure associated with *msqid* (see intro (2)).

Msg qnum is incremented by 1.

Msg lspid is set equal to the process ID of the calling process.

Msg stime is set equal to the current time.

Msgrcv reads a message from the queue associated with the message queue identifier specified by msqid and places it in the structure pointed to by msgp. (READ) This structure is composed of the following members:

long mtype; /\* message type \*/
char mtext[]; /\* message text \*/

Mtype is the received message's type as specified by the sending process. Mtext is the text of the message. Msgsz specifies the size in bytes of mtext. The received message is truncated to msgsz bytes if it is larger than msgsz and (msgflg & MSG\_NOERROR) is "true". The truncated part of the message is lost and no indication of the truncation is given to the calling process.

Msgtyp specifies the type of message requested as follows:

If msgtyp is equal to 0, the first message on the queue is received.

If msgtyp is greater than 0, the first message of type msgtyp is received

If msgtyp is less than 0, the first message of the lowest type that is less than or equal to the absolute value of msgtyp is received.

Msgflg specifies the action to be taken if a message of the desired type is not on the queue. These are as follows:

If (msgflg & IPC\_NOWAIT) is "true", the calling process will return immediately with a return value of -1 and errno set to ENOMSG.

If (msgflg & IPC\_NOWAIT) is "false", the calling process will suspend execution until one of the following occurs:

A message of the desired type is placed on the queue.

Msqid is removed from the system. When this occurs, errno is set equal to EIDRM, and a value of -1 is returned.

The calling process receives a signal that is to be caught. In this case a message is not received and the calling process resumes execution in the manner prescribed in *signal*(2)).

Msgrcv will fail and no message will be received if one or more of the following are true:

[EINVAL] Msqid is not a valid message queue identifier.

[EACCES] Operation permission is denied to the calling process.

[EINVAL] Msgsz is less than 0.

[E2BIG] Mtext is greater than msgsz and (msgflg & MSG\_NOERROR)

is "false".

MSGOP(2) MSGOP(2)

[ENOMSG]

The queue does not contain a message of the desired type and

(msgtyp & IPC NOWAIT) is "true".

[EFAULT]

Msgp points to an illegal address.

Upon successful completion, the following actions are taken with respect to the data structure associated with *msqid* (see intro (2)).

Msg qnum is decremented by 1.

Msg\_lrpid is set equal to the process ID of the calling process.

Msg\_rtime is set equal to the current time.

### SEE ALSO

intro(2), msgctl(2), msgget(2), signal(2).

# DIAGNOSTICS

If msgsnd or msgrcv return due to the receipt of a signal, a value of -1 is returned to the calling process and errno is set to EINTR. If they return due to removal of msqid from the system, a value of -1 is returned and errno is set to EIDRM.

Upon successful completion, the return value is as follows:

Msgsnd returns a value of 0.

Msgrcv returns a value equal to the number of bytes actually placed into mtext.

Otherwise, a value of -1 is returned and *errno* is set to indicate the error.

NICE(2) NICE(2)

# NAME

nice - change priority of a process

# SYNOPSIS

int nice (incr)
int incr;

# DESCRIPTION

Nice adds the value of *incr* to the nice value of the calling process. A process's *nice value* is a positive number for which a more positive value results in lower CPU priority.

A maximum nice value of 39 and a minimum nice value of 0 are imposed by the system. Requests for values above or below these limits result in the nice value being set to the corresponding limit.

[EPERM]

Nice will fail and not change the nice value if *incr* is negative or greater than 40 and the effective user ID of the calling process is not super-user.

# SEE ALSO

exec(2).

nice(1) in the 3B2 Computer System User Reference Manual.

### DIAGNOSTICS

Upon successful completion, *nice* returns the new nice value minus 20. Otherwise, a value of -1 is returned and *errno* is set to indicate the error.

10/84 - 1 - 10/84

OPEN (2) OPEN (2)

NAME

open - open for reading or writing

#### **SYNOPSIS**

#include <fcntl.h>
int open (path, oflag [ , mode ] )
char \*path;
int oflag, mode;

### DESCRIPTION

Path points to a path name naming a file. Open opens a file descriptor for the named file and sets the file status flags according to the value of oflag. Oflag values are constructed by or-ing flags from the following list (only one of the first three flags below may be used):

O\_RDONLY

Open for reading only.

O\_WRONLY

Open for writing only.

O RDWR

Open for reading and writing.

O\_NDELAY

This flag may affect subsequent reads and writes. See *read* (2) and *write* (2).

When opening a FIFO with O\_RDONLY or O\_WRONLY set:

If O NDELAY is set:

An *open* for reading-only will return without delay. An *open* for writing-only will return an error if no process currently has the file open for reading.

If O\_NDELAY is clear:

An *open* for reading-only will block until a process opens the file for writing. An *open* for writing-only will block until a process opens the file for reading.

When opening a file associated with a communication line:

If O NDELAY is set:

The open will return without waiting for carrier.

If O NDELAY is clear:

The open will block until carrier is present.

O APPEND

If set, the file pointer will be set to the end of the file prior to each write.

each write

O SYNC

When opening a regular file, this flag affects subsequent writes. If set, each write(2) will wait for both the file data and file status to be physically updated.

O CREAT

If the file exists, this flag has no effect. Otherwise, the owner ID of the file is set to the effective user ID of the process, the group ID of the file is set to the effective group ID of the process, and the low-order 12 bits of the file mode are set to the value of *mode* modified as follows (see *creat*(2)):

All bits set in the file mode creation mask of the process are cleared. See *umask* (2).

The "save text image after execution bit" of the mode is cleared. See *chmod* (2).

O TRUNC

If the file exists, its length is truncated to 0 and the mode and owner are unchanged.

OPEN (2) OPEN (2)

O\_EXCL If O\_EXCL and O\_CREAT are set, open will fail if the file exists.

The file pointer used to mark the current position within the file is set to the beginning of the file.

The new file descriptor is set to remain open across exec system calls. See fcntl(2).

The named file is opened unless one or more of the following are true:

[ENOTDIR]	A component of the path prefix is not a directory.
[ENOENT]	O_CREAT is not set and the named file does not exist.

[EACCES] A component of the path prefix denies search permission.

[EACCES] Oflag permission is denied for the named file.

[EISDIR] The named file is a directory and oflag is write or read/write.

[EROFS] The named file resides on a read-only file system and oflag is

write or read/write.

[EMFILE] Twenty (20) file descriptors are currently open.

[ENXIO] The named file is a character special or block special file, and

the device associated with this special file does not exist.

[ETXTBSY] The file is a pure procedure (shared text) file that is being

executed and oflag is write or read/write.

[EFAULT] Path points outside the allocated address space of the process.

[EEXIST] O\_CREAT and O\_EXCL are set, and the named file exists.

[ENXIO] O\_NDELAY is set, the named file is a FIFO, O\_WRONLY is

set, and no process has the file open for reading.

[EINTR] A signal was caught during the open system call.

[ENFILE] The system file table is full.

### SEE ALSO

chmod(2), close(2), creat(2), dup(2), fcntl(2), lseek(2), read(2), umask(2), write(2).

### DIAGNOSTICS

Upon successful completion, the file descriptor is returned. Otherwise, a value of -1 is returned and *errno* is set to indicate the error.

PAUSE(2) PAUSE(2)

NAME

pause - suspend process until signal

**SYNOPSIS** 

pause ()

# DESCRIPTION

Pause suspends the calling process until it receives a signal. The signal must be one that is not currently set to be ignored by the calling process.

If the signal causes termination of the calling process, pause will not return.

If the signal is caught by the calling process and control is returned from the signal-catching function (see signal(2)), the calling process resumes execution from the point of suspension; with a return value of -1 from pause and errno set to EINTR.

# SEE ALSO

alarm(2), kill(2), signal(2), wait(2).

PIPE(2)

# NAME

pipe - create an interprocess channel

### **SYNOPSIS**

int pipe (fildes)
int fildes[2];

### DESCRIPTION

Pipe creates an I/O mechanism called a pipe and returns two file descriptors, fildes[0] and fildes[1]. Fildes[0] is opened for reading and fildes[1] is opened for writing.

Up to 5120 bytes of data are buffered by the pipe before the writing process is blocked. A read only file descriptor fildes[0] accesses the data written to fildes[1] on a first-in-first-out (FIFO) basis.

[EMFILE]

Pipe will fail if 19 or more file descriptors are currently open.

[ENFILE]

The system file table is full.

### SEE ALSO

read(2), write(2).

sh(1) in the 3B2 Computer System User Reference Manual.

# DIAGNOSTICS

Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned and *errno* is set to indicate the error.

PLOCK(2) PLOCK(2)

### NAME

plock - lock process, text, or data in memory

#### SYNOPSIS

#include <sys/lock.h>

int plock (op)

int op;

# DESCRIPTION

Plock allows the calling process to lock its text segment (text lock), its data segment (data lock), or both its text and data segments (process lock) into memory. Locked segments are immune to all routine swapping. Plock also allows these segments to be unlocked. The effective user ID of the calling process must be super-user to use this call. Op specifies the following:

PROCLOCK - lock text and data segments into memory (process lock)

TXTLOCK - lock text segment into memory (text lock)

DATLOCK - lock data segment into memory (data lock)

UNLOCK - remove locks

*Plock* will fail and not perform the requested operation if one or more of the following are true:

[EPERM] The effective user ID of the calling process is not super-user.

[EINVAL] Op is equal to PROCLOCK and a process lock, a text lock, or a

data lock already exists on the calling process.

[EINVAL] Op is equal to TXTLOCK and a text lock, or a process lock

already exists on the calling process.

[EINVAL] Op is equal to DATLOCK and a data lock, or a process lock

already exists on the calling process.

[EINVAL] Op is equal to UNLOCK and no type of lock exists on the cal-

ling process.

# SEE ALSO

exec(2), exit(2), fork(2).

### DIAGNOSTICS

Upon successful completion, a value of 0 is returned to the calling process. Otherwise, a value of -1 is returned and errno is set to indicate the error.

PROFIL(2) PROFIL(2)

**NAME** 

profil - execution time profile

### SYNOPSIS

void profil (buff, bufsiz, offset, scale) char \*buff; int bufsiz, offset, scale;

### DESCRIPTION

Buff points to an area of core whose length (in bytes) is given by bufsiz. After this call, the user's program counter (pc) is examined each clock tick (60th second); offset is subtracted from it, and the result multiplied by scale. If the resulting number corresponds to a word inside buff, that word is incremented.

The scale is interpreted as an unsigned, fixed-point fraction with binary point at the left: 0177777 (octal) gives a 1-1 mapping of pc's to words in buff; 077777 (octal) maps each pair of instruction words together. 02(octal) maps all instructions onto the beginning of buff (producing a non-interrupting core clock).

Profiling is turned off by giving a scale of 0 or 1. It is rendered ineffective by giving a bufsiz of 0. Profiling is turned off when an exec is executed, but remains on in child and parent both after a fork. Profiling will be turned off if an update in buff would cause a memory fault.

#### SEE ALSO

monitor(3C).

prof(1) in the 3B2 Computer System Extended Software Generation Utilities.

### DIAGNOSTICS

Not defined.

PTRACE(2) PTRACE(2)

NAME

ptrace - process trace

**SYNOPSIS** 

int ptrace (request, pid, addr, data); int request, pid, addr, data;

#### DESCRIPTION

Ptrace provides a means by which a parent process may control the execution of a child process. Its primary use is for the implementation of breakpoint debugging; see sdb(1). The child process behaves normally until it encounters a signal (see signal(2) for the list), at which time it enters a stopped state and its parent is notified via wait(2). When the child is in the stopped state, its parent can examine and modify its "core image" using ptrace. Also, the parent can cause the child either to terminate or continue, with the possibility of ignoring the signal that caused it to stop.

The request argument determines the precise action to be taken by ptrace and is one of the following:

This request must be issued by the child process if it is to be traced by its parent. It turns on the child's trace flag that stipulates that the child should be left in a stopped state upon receipt of a signal rather than the state specified by func; see signal (2). The pid, addr, and data arguments are ignored, and a return value is not defined for this request. Peculiar results will ensue if the parent does not expect to trace the child.

The remainder of the requests can only be used by the parent process. For each, pid is the process ID of the child. The child must be in a stopped state before these requests are made.

- 1, 2 With these requests, the word at location addr in the address space of the child is returned to the parent process. If I and D space are separated, request 1 returns a word from I space, and request 2 returns a word from D space. If I and D space are not separated, either request 1 or request 2 may be used with equal results. The data argument is ignored. These two requests will fail if addr is not the start address of a word, in which case a value of -1 is returned to the parent process and the parent's errno is set to EIO.
- With this request, the word at location addr in the child's USER area in the system's address space (see <sys/user.h>) is returned to the parent process. The data argument is ignored. This request will fail if addr is not the start address of a word or is outside the USER area, in which case a value of -1 is returned to the parent process and the parent's errno is set to EIO.
- 4, 5 With these requests, the value given by the *data* argument is written into the address space of the child at location *addr*. If I and D space are separated, request 4 writes a word into I space, and request 5 writes a word into D space. If I and D space are not separated, either request 4 or request 5 may be used with equal results. Upon successful completion, the value written into the address space of the child is returned to the parent. These two requests will fail if *addr* is a location in a pure procedure space and another process is executing in that space, or *addr* is not the start address of a word. Upon failure a value of -1 is returned to the parent process and the parent's *errno* is set to EIO.

PTRACE(2) PTRACE(2)

With this request, a few entries in the child's USER area can be written. *Data* gives the value that is to be written and *addr* is the location of the entry. The few entries that can be written are:

the general registers

the condition codes of the Processor Status Word.

- 7 This request causes the child to resume execution. If the data argument is 0, all pending signals including the one that caused the child to stop are canceled before it resumes execution. If the data argument is a valid signal number, the child resumes execution as if it had incurred that signal, and any other pending signals are canceled. The addr argument must be equal to 1 for this request. Upon successful completion, the value of data is returned to the parent. This request will fail if data is not 0 or a valid signal number, in which case a value of -1 is returned to the parent process and the parent's errno is set to EIO.
- 8 This request causes the child to terminate with the same consequences as *exit* (2).
- This request sets the trace bit in the Processor Status Word of the child and then executes the same steps as listed above for request 7. The trace bit causes an interrupt upon completion of one machine instruction. This effectively allows single stepping of the child.

To forestall possible fraud, *ptrace* inhibits the set-user-id facility on subsequent *exec*(2) calls. If a traced process calls *exec*, it will stop before executing the first instruction of the new image showing signal SIGTRAP.

### General Errors

Ptrace will in general fail if one or more of the following are true:

[EIO]

Request is an illegal number.

[ESRCH]

Pid identifies a child that does not exist or has not executed a ptrace with request 0.

# SEE ALSO

exec(2), signal(2), wait(2).

sdb(1) in the 3B2 Computer System Extended Software Generation Utilities.

READ(2) READ(2)

### NAME

read - read from file

### SYNOPSIS

int read (fildes, buf, nbyte) int fildes; char \*buf; unsigned nbyte;

#### DESCRIPTION

Fildes is a file descriptor obtained from a creat, open, dup, fcntl, or pipe system call.

Read attempts to read nbyte bytes from the file associated with fildes into the buffer pointed to by buf.

On devices capable of seeking, the *read* starts at a position in the file given by the file pointer associated with *fildes*. Upon return from *read*, the file pointer is incremented by the number of bytes actually read.

Devices that are incapable of seeking always read from the current position. The value of a file pointer associated with such a file is undefined.

Upon successful completion, *read* returns the number of bytes actually read and placed in the buffer; this number may be less than *nbyte* if the file is associated with a communication line (see *ioctl*(2) and *termio*(7)), or if the number of bytes left in the file is less than *nbyte* bytes. A value of 0 is returned when an end-of-file has been reached.

When attempting to read from an empty pipe (or FIFO):

If O\_NDELAY is set, the read will return a 0.

If O\_NDELAY is clear, the read will block until data is written to the file or the file is no longer open for writing.

When attempting to read a file associated with a tty that has no data currently available:

If O\_NDELAY is set, the read will return a 0.

If O\_NDELAY is clear, the read will block until data becomes available.

Read will fail if one or more of the following are true:

[EBADF]

Fildes is not a valid file descriptor open for reading.

[EFAULT]

Buf points outside the allocated address space.

[EINTR]

A signal was caught during the read system call.

### SEE ALSO

creat(2), dup(2), fcntl(2), ioctl(2), open(2), pipe(2). termio(7) in the 3B2 Computer System Administration Utilities Guide.

### DIAGNOSTICS

Upon successful completion a non-negative integer is returned indicating the number of bytes actually read. Otherwise, a -1 is returned and *errno* is set to indicate the error.

SEMCTL(2) SEMCTL(2)

```
NAME
semctl — semaphore control operations

SYNOPSIS

#include <sys/types.h>
#include <sys/sem.h>

int semctl (semid, semnum, cmd, arg)
int semid, cmd;
int semnum;
union semun {
   int val;
   struct semid_ds *buf;
   ushort *array;
} arg;
```

### DESCRIPTION

Semctl provides a variety of semaphore control operations as specified by cmd.

The following *cmds* are executed with respect to the semaphore specified by *semid* and *semnum*:

GETVAL Return the value of semval (see intro(2)). {READ}

SETVAL Set the value of semval to arg.val. {ALTER} When this

cmd is successfully executed, the semadj value corresponding to the specified semaphore in all processes

is cleared.

GETPID Return the value of sempid. {READ}

GETNCNT Return the value of semnent. {READ}

GETZCNT Return the value of semzont. {READ}

The following *cmd*s return and set, respectively, every semval in the set of semaphores.

GETALL Place semvals into array pointed to by arg.array.

{READ}

SETALL Set semvals according to the array pointed to by

arg.array. {ALTER} When this cmd is successfully executed the semadj values corresponding to each specified

semaphore in all processes are cleared.

The following cmds are also available:

IPC\_STAT Place the current value of each member of the data structure associated with *semid* into the structure pointed to by *arg.buf*. The contents of this structure are defined

in intro(2). {READ}

IPC\_SET Set the value of the following members of the data structure associated with *semid* to the corresponding value

found in the structure pointed to by arg.buf:

sem\_perm.uid sem\_perm.gid

sem perm.mode /\* only low 9 bits \*/

This cmd can only be executed by a process that has an effective user ID equal to either that of super-user or to the value of sem\_perm.uid in the data structure associ-

ated with semid.

SEMCTL(2) SEMCTL(2)

IPC\_RMID Remove the semaphore identifier specified by semid from

the system and destroy the set of semaphores and data structure associated with it. This cmd can only be executed by a process that has an effective user ID equal to either that of super-user or to the value of sem\_perm.uid

in the data structure associated with semid.

Semctl will fail if one or more of the following are true:

[EINVAL] Semid is not a valid semaphore identifier.

[EINVAL] Semnum is less than zero or greater than sem\_nsems.

[EINVAL] Cmd is not a valid command.

[EACCES] Operation permission is denied to the calling process

(see intro(2)).

[ERANGE] Cmd is SETVAL or SETALL and the value to which

semval is to be set is greater than the system imposed

maximum.

[EPERM] Cmd is equal to IPC\_RMID or IPC\_SET and the

effective user ID of the calling process is not equal to that of super-user and it is not equal to the value of sem perm.uid in the data structure associated with

semid.

[EFAULT] Arg.buf points to an illegal address.

SEE ALSO

intro(2), semget(2), semop(2).

DIAGNOSTICS

Upon successful completion, the value returned depends on cmd as follows:

GETVAL

The value of semval.

**GETPID** 

The value of sempid. The value of semnent.

GETNCNT GETZCNT

The value of semicint.

GEIZCNI

The value of semzer

All others A value of 0.

Otherwise, a value of -1 is returned and *errno* is set to indicate the error.

SEMGET (2) SEMGET (2)

#### NAME

semget - get set of semaphores

#### SYNOPSIS

#include <sys/types.h>
#include <sys/ipc.h>
#include <sys/sem.h>
int semget (key, nsems, semflg)
key t key;

int nsems, semflg;

### **DESCRIPTION**

Semget returns the semaphore identifier associated with key.

A semaphore identifier and associated data structure and set containing *nsems* semaphores (see *intro*(2)) are created for *key* if one of the following are true:

Key is equal to IPC\_PRIVATE.

Key does not already have a semaphore identifier associated with it, and (semflg & IPC\_CREAT) is "true".

Upon creation, the data structure associated with the new semaphore identifier is initialized as follows:

Sem\_perm.cuid, sem\_perm.uid, sem\_perm.cgid, and sem\_perm.gid are set equal to the effective user ID and effective group ID, respectively, of the calling process.

The low-order 9 bits of **sem\_perm.mode** are set equal to the low-order 9 bits of *semflg*.

Sem\_nsems is set equal to the value of nsems.

Sem\_otime is set equal to 0 and sem\_ctime is set equal to the current time.

Semget will fail if one or more of the following are true:

[EINVAL] Nsems is either less than or equal to zero or greater than the

system-imposed limit.

[EACCES] A semaphore identifier exists for key, but operation permis-

sion (see intro(2)) as specified by the low-order 9 bits of

semflg would not be granted.

[EINVAL] A semaphore identifier exists for key, but the number of

semaphores in the set associated with it is less than nsems and

nsems is not equal to zero.

[ENOENT] A semaphore identifier does not exist for key and (semflg &

IPC CREAT) is "false".

[ENOSPC] A semaphore identifier is to be created but the system-

imposed limit on the maximum number of allowed semaphore

identifiers system wide would be exceeded.

[ENOSPC] A semaphore identifier is to be created but the system-

imposed limit on the maximum number of allowed semaphores

system wide would be exceeded.

[EEXIST] A semaphore identifier exists for key but ( (semflg &

IPC\_CREAT) and ( semflg & IPC\_EXCL) ) is "true".

SEMGET (2) SEMGET (2)

# SEE ALSO

intro(2), semctl(2), semop(2).

# DIAGNOSTICS

Upon successful completion, a non-negative integer, namely a semaphore identifier, is returned. Otherwise, a value of -1 is returned and *errno* is set to indicate the error.

SEMOP(2) SEMOP(2)

```
NAME
```

```
semop - semaphore operations
```

### **SYNOPSIS**

```
#include <sys/types.h>
#include <sys/ipc.h>
#include <sys/sem.h>
int semop (semid, sops, nsops)
int semid;
struct sembuf **sops;
int nsops;
```

#### DESCRIPTION

Semop is used to automatically perform an array of semaphore operations on the set of semaphores associated with the semaphore identifier specified by semid. Sops is a pointer to the array of semaphore-operation structures. Nsops is the number of such structures in the array. The contents of each structure includes the following members:

```
short sem_num; /* semaphore number */
short sem_op; /* semaphore operation */
short sem_flg; /* operation flags */
```

Each semaphore operation specified by sem\_op is performed on the corresponding semaphore specified by semid and sem\_num.

Sem op specifies one of three semaphore operations as follows:

If  $sem\_op$  is a negative integer, one of the following will occur:  $\{ALTER\}$ 

If semval (see *intro*(2)) is greater than or equal to the absolute value of *sem\_op*, the absolute value of *sem\_op* is subtracted from semval. Also, if (*sem\_flg & SEM\_UNDO*) is "true", the absolute value of *sem\_op* is added to the calling process's semadj value (see *exit*(2)) for the specified semaphore.

If semval is less than the absolute value of <code>sem\_op</code> and <code>(sem\_flg & IPC\_NOWAIT)</code> is "true", <code>semop</code> will return immediately.

If semval is less than the absolute value of sem\_op and (sem\_flg & IPC\_NOWAIT) is "false", semop will increment the semnent associated with the specified semaphore and suspend execution of the calling process until one of the following conditions occur.

Semval becomes greater than or equal to the absolute value of  $sem\_op$ . When this occurs, the value of semncnt associated with the specified semaphore is decremented, the absolute value of  $sem\_op$  is subtracted from semval and, if  $(sem\_flg \& SEM\_UNDO)$  is "true", the absolute value of  $sem\_op$  is added to the calling process's semadj value for the specified semaphore.

The semid for which the calling process is awaiting action is removed from the system (see semctl(2)). When this occurs, errno is set equal to EIDRM, and a value of -1 is returned.

SEMOP(2) SEMOP(2)

> The calling process receives a signal that is to be caught. When this occurs, the value of semnent associated with the specified semaphore is decremented, and the calling process resumes execution in the manner prescribed in signal (2).

If sem\_op is a positive integer, the value of sem\_op is added to semval and, if (sem\_flg & SEM\_UNDO) is "true", the value of sem\_op is subtracted from the calling process's semadj value for the specified semaphore. {ALTER}

If sem op is zero, one of the following will occur: {READ}

If semval is zero, semop will return immediately.

If semval is not equal to zero and (sem\_flg & IPC\_NOWAIT) is "true", semop will return immediately.

If semval is not equal to zero and (sem flg & IPC\_NOWAIT) is "false", semop will increment the semzent associated with the specified semaphore and suspend execution of the calling process until one of the following occurs:

Semval becomes zero, at which time the value of semzent associated with the specified semaphore is decremented.

The semid for which the calling process is awaiting action is removed from the system. When this occurs, errno is set equal to EIDRM, and a value of -1 is returned.

The calling process receives a signal that is to be caught. When this occurs, the value of semzent associated with the specified semaphore is decremented, and the calling process resumes execution in the manner prescribed in signal (2).

Semop will fail if one or more of the following are true for any of the semaphore operations specified by sops:

[EINVAL]	Semid is not a valid semaphore identifier.		
[EFBIG]	Sem_num is less than zero or greater than or equal to the number of semaphores in the set associated with semid.		
[E2BIG]	Nsops is greater than the system-imposed maximum.		
[EACCES]	Operation permission is denied to the calling process (see $intro(2)$ ).		
[EAGAIN]	The operation would result in suspension of the calling process but (sem_flg & IPC_NOWAIT) is "true".		
[ENOSPC]	The limit on the number of individual processes requesting an SEM_UNDO would be exceeded.		
[EINVAL]	The number of individual semaphores for which the calling process requests a SEM_UNDO would exceed the limit.		
[ERANGE]	An operation would cause a semval to overflow the system-		

[ERANGE] An operation would cause a semadj value to overflow the

system-imposed limit.

Sops points to an illegal address. [EFAULT]

imposed limit.

Upon successful completion, the value of sempid for each semaphore specified in the array pointed to by sops is set equal to the process ID of the calling process.

SEMOP(2) SEMOP(2)

### SEE ALSO

exec(2), exit(2), fork(2), intro(2), semctl(2), semget(2).

#### DIAGNOSTICS

If semop returns due to the receipt of a signal, a value of -1 is returned to the calling process and *errno* is set to EINTR. If it returns due to the removal of a semid from the system, a value of -1 is returned and *errno* is set to EIDRM.

Upon successful completion, the value of semval at the time of the call for the last operation in the array pointed to by sops is returned. Otherwise, a value of -1 is returned and errno is set to indicate the error.

SETPGRP(2) SETPGRP(2)

NAME

setpgrp - set process group ID

SYNOPSIS

int setpgrp ()

DESCRIPTION

Setpgrp sets the process group ID of the calling process to the process ID of the calling process and returns the new process group ID.

SEE ALSO

exec(2), fork(2), getpid(2), intro(2), kill(2), signal(2).

DIAGNOSTICS

Setpgrp returns the value of the new process group ID.

SETUID(2) SETUID(2)

#### NAME

setuid, setgid - set user and group IDs

### **SYNOPSIS**

int setuid (uid) int uid:

int setgid (gid)

int gid;

# DESCRIPTION

Setuid (setgid) is used to set the real user (group) ID and effective user (group) ID of the calling process.

If the effective user ID of the calling process is super-user, the real user (group) ID and effective user (group) ID are set to uid (gid).

If the effective user ID of the calling process is not super-user, but its real user (group) ID is equal to *uid* (gid), the effective user (group) ID is set to *uid* (gid).

If the effective user ID of the calling process is not super-user, but the saved set-user (group) ID from exec(2) is equal to uid (gid), the effective user (group) ID is set to uid (gid).

Setuid (setgid) will fail if the real user (group) ID of the calling process is not equal to uid (gid) and its effective user ID is not super-user. [EPERM]

The *uid* is out of range. [EINVAL]

# SEE ALSO

getuid(2), intro(2).

### **DIAGNOSTICS**

Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned and *errno* is set to indicate the error.

10/84

SHMCTL(2) SHMCTL(2)

### NAME

shmctl - shared memory control operations

### SYNOPSIS

#include <sys/types.h>
#include <sys/page.h>
#include <sys/ipc.h>
#include <sys/shm.h>
int shmctl (shmid, cmd, buf)
int shmid, cmd;
struct shmid ds \*buf;

## DESCRIPTION

Shmctl provides a variety of shared memory control operations as specified by cmd. The following cmds are available:

IPC\_STAT Place the current value of each member of the data structure associated with *shmid* into the structure pointed to by *buf*. The contents of this structure are defined in [EINVAL] *intro*(2). {READ}

Set the value of the following members of the data structure associated with *shmid* to the corresponding value found in the structure pointed to by *buf*:

shm\_perm.uid shm\_perm.gid

shm perm.mode /\* only low 9 bits \*/

This *cmd* can only be executed by a process that has an effective user ID equal to either that of super user or to the value of **shm\_perm[i].uid** in the data structure associated with *shmid*.

IPC\_RMID

Remove the shared memory identifier specified by shmid from the system and destroy the shared memory segment and data structure associated with it. This cmd can only be executed by a process that has an effective user ID equal to either that of super user or to the value of shm\_perm[i].uid in the data structure associated with shmid.

SHM\_LOCK Lock the shared memory segment specified by *shmid* in memory. This *cmd* can only be executed by a process that has an effective usr ID equal to super user.

# SHM UNLOCK

Unlock the shared memory segment specified by *shmid*. This *cmd* can only be executed by a process that has an effective usr ID equal to super user.

Shmctl will fail if one or more of the following are true:

### [EINVAL]

Shmid is not a valid shared memory identifier.

### [EINVAL]

Cmd is not a valid command.

### [EACCESS]

Cmd is equal to IPC\_STAT and {READ} operation permission is denied to the calling process [see intro(2)].

### [EPERM]

Cmd is equal to IPC RMID or IPC SET and the effective user

SHMCTL(2)

ID of the calling process is not equal to that of super user and it is not equal to the value of **shm\_perm.uid** in the data structure associated with *shmid*.

### [EPERM]

Cmd is equal to SHM\_LOCK or SHM\_UNLOCK and the effective user ID of the calling process is not equal to that of super user.

# [EINVAL]

Cmd is equal to SHM\_UNLOCK and the shared-memory segment specified by shmid is not locked in memory.

# [EFAULT]

Buf points to an illegal address.

# SEE ALSO

shmget(2), shmop(2).

# DIAGNOSTICS

Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned and *errno* is set to indicate the error.

SHMGET(2) SHMGET(2)

#### NAME

shmget – get shared memory segment

### **SYNOPSIS**

```
#include <sys/types.h>
#include <sys/page.h>
#include <sys/ipc.h>
#include <sys/shm.h>
int shmget (key, size, shmflg)
key_t key;
int size, shmflg;
```

### DESCRIPTION

Shared returns the shared memory identifier associated with key.

A shared memory identifier and associated data structure and shared memory segment of size size bytes (see intro(2)) are created for key if one of the following are true:

Key is equal to IPC PRIVATE.

Key does not already have a shared memory identifier associated with it, and (shmflg & IPC CREAT) is "true".

Upon creation, the data structure associated with the new shared memory identifier is initialized as follows:

> Shm perm.cuid, shm\_perm.uid, shm\_perm.cgid, and shm\_perm.gid are set equal to the effective user ID and effective group ID, respectively, of the calling process.

The low-order 9 bits of shm\_perm.mode are set equal to the low-order 9 bits of shmflg. Shm segsz is set equal to the value of size.

Shm lpid, shm\_nattch, shm\_atime, and shm\_dtime are set equal to 0.

Shm ctime is set equal to the current time.

Shmget will fail if one or more of the following are true:

[EINVAL]	Size is less than the system-imposed minimum or greater than
	the system-imposed maximum

[EACCES] A shared memory identifier exists for key but operation permission (see intro(2)) as specified by the low-order 9 bits of

shmflg would not be granted.

[EINVAL] A shared memory identifier exists for key but the size of the segment associated with it is less than size and size is not equal to zero.

[ENOENT] A shared memory identifier does not exist for key and (shmflg & IPC CREAT) is "false".

[ENOSPC] A shared memory identifier is to be created but the system-

imposed limit on the maximum number of allowed shared memory identifiers system wide would be exceeded.

A shared memory identifier and associated shared memory [ENOMEM]

segment are to be created but the amount of available memory is not sufficient to fill the request.

A shared memory identifier exists for key but ( (shmflg & [EEXIST]

IPC\_CREAT) and ( shmflg & IPC\_EXCL) ) is "true".

SHMGET(2) SHMGET(2)

SEE ALSO

intro(2), shmctl(2), shmop(2).

# DIAGNOSTICS

Upon successful completion, a non-negative integer, namely a shared memory identifier is returned. Otherwise, a value of -1 is returned and *errno* is set to indicate the error.

#### NAME

shmop - shared memory operations

#### SYNOPSIS

#include <sys/types.h> #include <sys/page.h> #include <sys/ipc.h> #include <sys/shm.h>

char \*shmat (shmid, shmaddr, shmflg)

char \*shmaddr int shmflg;

int shmdt (shmaddr) char \*shmaddr

#### DESCRIPTION

Shmat attaches the shared memory segment associated with the shared memory identifier specified by shmid to the data segment of the calling process. The segment is attached at the address specified by one of the following criteria:

> If shmaddr is equal to zero, the segment is attached at the first available address as selected by the system.

> If shmaddr is not equal to zero and (shmflg & SHM\_RND) is "true", the segment is attached at the address given by (shmaddr - (shmaddr modulus SHMLBA)).

> If shmaddr is not equal to zero and (shmflg & SHM\_RND) is "false", the segment is attached at the address given by shmaddr.

The segment is attached for reading if (shmflg & SHM\_RDONLY) is "true" {READ}, otherwise it is attached for reading and writing {READ/WRITE}.

Shmat will fail and not attach the shared memory segment if one or more of the following are true:

Shmid is not a valid shared memory identifier. [EINVAL]

Operation permission is denied to the calling process (see [EACCES]

intro(2).

The available data space is not large enough to accommodate [ENOMEM]

the shared memory segment.

Shmaddr is not equal to zero, and the value of (shmaddr -[EINVAL]

(shmaddr modulus SHMLBA)) is an illegal address.

Shmaddr is not equal to zero, (shmflg & SHM\_RND) is [EINVAL]

"false", and the value of shmaddr is an illegal address.

The number of shared memory segments attached to the cal-[EMFILE] ling process would exceed the system-imposed limit.

Shmdt detaches from the calling process's data segment the [EINVAL] shared memory segment located at the address specified by

shmaddr.

[EINVAL] Shmdt will fail and not detach the shared memory segment if

shmaddr is not the data segment start address of a shared

memory segment.

SHMOP(2) SHMOP(2)

# SEE ALSO

exec(2), exit(2), fork(2), intro(2), shmctl(2), shmget(2).

# DIAGNOSTICS

Upon successful completion, the return value is as follows:

Shmat returns the data segment start address of the attached shared memory segment.

Shmdt returns a value of 0.

Otherwise, a value of -1 is returned and *errno* is set to indicate the error.

SIGNAL(2) SIGNAL(2)

#### NAME

signal - specify what to do upon receipt of a signal

# **SYNOPSIS**

```
#include <signal.h>
int (*signal (sig, func))()
int sig;
void (*func)();
```

### DESCRIPTION

Signal allows the calling process to choose one of three ways in which it is possible to handle the receipt of a specific signal. Sig specifies the signal and func specifies the choice.

Sig can be assigned any one of the following except SIGKILL:

SIGHUP	01	hangup
SIGINT	02	interrupt
SIGQUIT	03*	quit
SIGILL	04*	illegal instruction (not reset when caught)
SIGTRAP	05*	trace trap (not reset when caught)
SIGIOT	06*	IOT instruction
SIGEMT	07*	EMT instruction
SIGFPE	08*	floating point exception
SIGKILL	09	kill (cannot be caught or ignored)
SIGBUS	10*	bus error
SIGSEGV	11*	segmentation violation
SIGSYS	12*	bad argument to system call
SIGPIPE	13	write on a pipe with no one to read it
<b>SIGALRM</b>	14	alarm clock
SIGTERM	15	software termination signal
SIGUSR1	16	user-defined signal 1
SIGUSR2	17	user-defined signal 2
SIGCLD	18	death of a child
		(see WARNING below)
SIGPWR	19	power fail
		(see WARNING below)

See below for the significance of the asterisk (\*) in the above list.

Func is assigned one of three values: SIG\_DFL, SIG\_IGN, or a function address. The actions prescribed by these values are as follows:

# SIG\_DFL - terminate process upon receipt of a signal

Upon receipt of the signal sig, the receiving process is to be terminated with all of the consequences outlined in exit(2). In addition a "core image" will be made in the current working directory of the receiving process if sig is one for which an asterisk appears in the above list and the following conditions are met:

The effective user ID and the real user ID of the receiving process are equal.

An ordinary file named **core** exists and is writable or can be created. If the file must be created, it will have the following properties:

- a mode of 0666 modified by the file creation mask (see *umask*(2))
- a file owner ID that is the same as the effective user ID of the receiving process.

SIGNAL(2) SIGNAL(2)

a file group ID that is the same as the effective group ID of the receiving process

SIG IGN - ignore signal

The signal sig is to be ignored.

Note: the signal SIGKILL cannot be ignored.

# function address - catch signal

Upon receipt of the signal sig, the receiving process is to execute the signal-catching function pointed to by func. The signal number sig will be passed as the only argument to the signal-catching function. Additional arguments are passed to the signal-catching function for hardware-generated signals. Before entering the signal-catching function, the value of func for the caught signal will be set to SIG\_DFL unless the signal is SIGILL, SIGTRAP, or SIGPWR.

Upon return from the signal-catching function, the receiving process will resume execution at the point it was interrupted.

When a signal that is to be caught occurs during a read, a write, an open, or an ioctl system call on a slow device (like a terminal; but not a file), during a pause system call, or during a wait system call that does not return immediately due to the existence of a previously stopped or zombie process, the signal catching function will be executed and then the interrupted system call may return a -1 to the calling process with errno set to EINTR.

Note: The signal SIGKILL cannot be caught.

A call to signal cancels a pending signal sig except for a pending SIGKILL signal.

Signal will fail if sig is an illegal signal number, including SIGKILL. [EINVAL]

#### SEE ALSO

kill(2), pause(2), ptrace(2), wait(2), setjmp(3C).

kill(1) in the 3B2 Computer System User Reference Manual.

# WARNING

Two other signals that behave differently than the signals described above exist in this release of the system; they are:

SIGCLD

18 death of a child (reset when caught)

SIGPWR

19 power fail (not reset when caught)

There is no guarantee that, in future releases of the UNIX system, these signals will continue to behave as described below; they are included only for compatibility with other versions of the UNIX system. Their use in new programs is strongly discouraged.

For these signals, func is assigned one of three values: SIG\_DFL, SIG\_IGN, or a function address. The actions prescribed by these values of are as follows:

SIG\_DFL - ignore signal

The signal is to be ignored.

#### SIG IGN - ignore signal

The signal is to be ignored. Also, if sig is SIGCLD, the calling process's child processes will not create zombie processes when they terminate; see exit(2).

# function address - catch signal

If the signal is SIGPWR, the action to be taken is the same as that described above for *func* equal to *function address*. The same is true if the signal is SIGCLD except, that while the process is

SIGNAL(2) SIGNAL(2)

executing the signal-catching function, any received SIGCLD signals will be queued and the signal-catching function will be continually reentered until the queue is empty.

The SIGCLD affects two other system calls (wait(2), and exit(2)) in the following ways:

wait If the func value of SIGCLD is set to SIG\_IGN and a wait is executed, the wait will block until all of the calling process's child processes terminate; it will then return a value of -1 with errno set to ECHILD.

exit If in the exiting process's parent process the func value of SIGCLD is set to SIG IGN, the exiting process will not create a zombie process.

When processing a pipeline, the shell makes the last process in the pipeline the parent of the proceeding processes. A process that may be piped into in this manner (and thus become the parent of other processes) should take care not to set SIGCLD to be caught.

# DIAGNOSTICS

Upon successful completion, signal returns the previous value of func for the specified signal sig. Otherwise, a value of -1 is returned and errno is set to indicate the error.

#### NAME

stat, fstat - get file status

### **SYNOPSIS**

#include <sys/types.h>
#include <sys/stat.h>
int stat (path, buf)
char \*path;
struct stat \*buf;
int fstat (fildes, buf)
int fildes;

struct stat \*buf;

#### DESCRIPTION

Path points to a path name naming a file. Read, write, or execute permission of the named file is not required, but all directories listed in the path name leading to the file must be searchable. Stat obtains information about the named file.

Similarly, *fstat* obtains information about an open file known by the file descriptor *fildes*, obtained from a successful *open*, *creat*, *dup*, *fcntl*, or *pipe* system call.

Buf is a pointer to a stat structure into which information is placed concerning the file.

The contents of the structure pointed to by buf include the following members:

```
/* File mode; see mknod(2) */
ushort
         st mode;
ino t
         st ino;
                        /* Inode number */
dev t
         st dev;
                        /* ID of device containing */
                        /* a directory entry for this file */
dev t
         st rdev;
                        /* ID of device */
                        /* This entry is defined only for */
                        /* character special or block special files */
short
         st nlink;
                        /* Number of links */
ushort
         st uid;
                       /* User ID of the file's owner */
ushort
         st gid;
                       /* Group ID of the file's group */
off t
         st size;
                       /* File size in bytes */
                       /* Time of last access */
time t
         st atime;
time t
         st mtime;
                       /* Time of last data modification */
time t
                       /* Time of last file status change */
         st ctime;
                       /* Times measured in seconds since */
                       /* 00:00:00 GMT, Jan. 1, 1970 */
```

st\_atime Time when file data was last accessed. Changed by the following system calls: creat(2), mknod(2), pipe(2), utime(2), and read(2).

st\_mtime Time when data was last modified. Changed by the following system calls: creat(2), mknod(2), pipe(2), utime(2), and write(2).

st\_ctime Time when file status was last changed. Changed by the following system calls: chmod(2), chown(2), creat(2), link(2), mknod(2), pipe(2), unlink(2), utime(2), and write(2).

Stat will fail if one or more of the following are true:

[ENOTDIR] A component of the path prefix is not a directory.

[ENOENT] The named file does not exist.

[EACCES] Search permission is denied for a component of the path prefix.

10/84

STAT(2) STAT(2)

[EFAULT] Buf or path points to an invalid address.

Fstat will fail if one or more of the following are true:

[EBADF] Filde

Fildes is not a valid open file descriptor.

[EFAULT]

Buf points to an invalid address.

# **SEE ALSO**

chmod(2), chown(2), creat(2), link(2), mknod(2), pipe(2), read(2), time(2), unlink(2), utime(2), write(2).

# DIAGNOSTICS

Upon successful completion a value of 0 is returned. Otherwise, a value of -1 is returned and *errno* is set to indicate the error.

STIME(2) STIME(2)

NAME

stime - set time

SYNOPSIS

int stime (tp) long \*tp;

# DESCRIPTION

Stime sets the system's idea of the time and date. Tp points to the value of time as measured in seconds from 00:00:00 GMT January 1, 1970.

[EPERM]

Stime will fail if the effective user ID of the calling process is not super-user.

# SEE ALSO

time(2).

# DIAGNOSTICS

Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned and *errno* is set to indicate the error.

SYNC(2) SYNC(2)

NAME

sync - update super block

**SYNOPSIS** 

void sync ()

# DESCRIPTION

Sync causes all information in memory that should be on disk to be written out. This includes modified super blocks, modified i-nodes, and delayed block I/O.

It should be used by programs which examine a file system, for example fsck, df, etc. It is mandatory before a boot.

The writing, although scheduled, is not necessarily complete upon return from sync.

SYS3B(2) SYS3B(2)

#### NAME

sys3b - machine specific function

### **SYNOPSIS**

```
#include <sys/sys3b.h>
int sys3b (cmd, arg1, arg2, arg3)
int cmd, arg1, arg2, arg3;
```

#### DESCRIPTION

Sys3b implements machine specific functions. The cmd argument determines the function performed. The number of arguments expected is dependent on the function.

#### Command S3BSYM

When cmd is S3BSYM, the symbol table created during a self-config boot process may be accessed. The symbols defined within the driver routines loaded and those created from the /etc/master file variable specifications are available via this command. Two arguments are expected; the first must be a pointer to a buffer into which the symbol table is copied, and the second must be an integer containing the total size of the buffer. The format of the symbol table is:

```
int
                   /* symbol size in bytes */
       size:
int
                   /* total number of symbols */
       nsyms;
                   /* for each symbol ... */
                         name of symbol, padded with */
char
       namell;
                  /*
                             ' ' to next sizeof(long) */
                  /*
                             boundary */
long
       value:
                          value of symbol */
```

Typically, the symbol table would be retrieved with two calls to sys3b. First, the size of the symbol table is obtained by calling sys3b with a buffer of one integer. This integer is then used to obtain a buffer large enough to contain the entire symbol table. The second invocation of sys3b with this newly obtained buffer retrieves the entire symbol table.

```
#include <sys/sys3b.h>
```

```
int size; /* size of buffer needed */
struct s3bsym *buffer; /* buffer pointer */

sys3b( S3BSYM, & size, sizeof(size) );
buffer = (struct s3bsym *) malloc( size );
sys3b( S3BSYM, buffer, size );
```

#### Command S3BCONF

When *cmd* is S3BCONF, the configuration table created during a self-config boot process may be accessed. This table contains the names and locations of the devices supported by the currently running UNIX system, the names of all software modules included in the system, and the names of all devices in the EDT that were ignored. Two arguments are expected; the first must be a pointer to a buffer into which the configuration table is copied, and the second must be an integer containing the total size of the buffer. The format of the configuration table is:

SYS3B(2) SYS3B(2)

```
/* total number of entries */
int
       ndev:
                      /* for each entry ... */
                            f timdat from file header */
long
       timestamp;
                      /*
char
       name[14];
                            name of device/module */
                      /*
char
                            configuration information */
       flag;
                      /*
                                0x80: device ignored */
                      /*
                                0x40: name[] is a driver */
                                0x20: name[] is a software module */
                      /* local bus address of device */
char
        board;
```

Typically, the configuration table would be retrieved with two calls to sys3b. First, the number of entries is obtained by calling sys3b with a buffer of one integer. This integer is then used to calculate and obtain a buffer large enough to contain the entire configuration table. The second invocation of sys3b with this newly obtained buffer retrieves the configuration table.

```
#include <sys/sys3b.h>
```

```
int count; /* total number of devices */
int size; /* size of buffer needed */
struct s3bconf *buffer; /* buffer pointer */

sys3b( S3BCONF, & count, sizeof(count) );
size = sizeof(int);
size += count * sizeof(struct s3bc);
buffer = (struct s3bconf *) malloc( size );
sys3b( S3BCONF, buffer, size );
```

## Command S3BBOOT

When cmd is S3BBOOT, the timestamp and boot program path name used for a self-config boot process may be accessed. The path name of the a.out format file which was booted, and the timestamp from the file header (see a.out(4)) are saved. One argument is expected; a pointer to a buffer into which the information is copied. The format of this information is:

```
long timestamp; /* f_timdat from file header */
char path[100]; /* path name */
```

This information would be retrieved with a single call to sys3b.

```
#include <sys/sys3b.h>
struct s3bboot buffer; /* buffer */
sys3b( S3BBOOT, & buffer );
```

## Command S3BAUTO

When *cmd* is S3BAUTO, no arguments are expected. This function returns a boolean value in answer to the question "was the last boot an auto-config boot or was a fully configured file booted?". The value returned is zero if a fully configured file (such as /unix) was booted. The integer value 1 is returned if the preceeding boot was an auto-config boot.

```
SEE ALSO
```

sync(2), a.out(4).

TIME(2)

## NAME

time - get time

## SYNOPSIS

long time ((long \*) 0)

long time (tloc) long \*tloc;

## DESCRIPTION

Time returns the value of time in seconds since 00:00:00 GMT, January 1, 1970.

If *tloc* (taken as an integer) is non-zero, the return value is also stored in the location to which *tloc* points.

[EFAULT] Time will fail if tloc points to an illegal address.

## SEE ALSO

stime(2).

# DIAGNOSTICS

Upon successful completion, time returns the value of time. Otherwise, a value of -1 is returned and errno is set to indicate the error.

TIMES (2) TIMES (2)

## NAME

times - get process and child process times

## **SYNOPSIS**

```
#include <sys/types.h>
#include <sys/times.h>
long times (buffer)
struct tms *buffer;
```

## DESCRIPTION

Times fills the structure pointed to by buffer with time-accounting information. The following are the contents of this structure:

```
struct tms {
    time_t tms_utime;
    time_t tms_stime;
    time_t tms_cutime;
    time_t tms_cutime;
};
```

This information comes from the calling process and each of its terminated child processes for which it has executed a wait. All times are in 60ths of a second on DEC processors, 100ths of a second on AT&T processors.

Tms\_utime is the CPU time used while executing instructions in the user space of the calling process.

Tms stime is the CPU time used by the system on behalf of the calling process.

Tms\_cutime is the sum of the tms\_utimes and tms\_cutimes of the child processes.

Tms\_cstime is the sum of the tms\_stimes and tms\_cstimes of the child processes.

[EFAULT] Times will fail if buffer points to an illegal address.

## SEE ALSO

exec(2), fork(2), time(2), wait(2).

## DIAGNOSTICS

Upon successful completion, *times* returns the elapsed real time, in 60ths (100ths) of a second, since an arbitrary point in the past (e.g., system start-up time). This point does not change from one invocation of *times* to another. If *times* fails, a -1 is returned and *errno* is set to indicate the error.

10/84 - 1 - 10/84

UADMIN(2) UADMIN(2)

NAME

uadmin - administrative control

SYNOPSIS

#include <sys/uadmin.h>

int uadmin (cmd, fcn, mdep)

int cmd, fcn, mdep;

#### DESCRIPTION

*Uadmin* provides control for basic administrative functions. This system call is tightly coupled to the system administrative procedures and is not intended for general use. The argument *mdep* is provided for machine-dependent use and is not defined here.

The commands available as specified by cmd are:

A\_SHUTDOWN The system is shutdown. All user processes are killed, the

buffer cache is flushed, and the root file system is unmounted. The action to be taken after the system is shutdown is specified by fcn. The functions are generic, on specific

machines the hardware capabilities will vary.

AD\_HALT Halt the processor and turn off power.

AD\_BOOT Reboot the system, use /unix.

AD\_IBOOT Interactive reboot, prompt for system name.

A\_REBOOT The system stops immediately without any further processing.

The action io be taken next is specified by fcn as above.

A\_REMOUNT The root file system is mounted again after having been fixed. This should only be used during the startup process.

Uadmin will fail if any of the following are true:

[EPERM] The effective user ID is not super-user.

## DIAGNOSTICS

Upon successful completion, the value returned depends on cmd as follows:

A\_SHUTDOWN Never returns.

A\_REBOOT Never returns.

A\_REMOUNT (

Otherwise, a value of -1 is returned and errno is set to indicate the error. mount(2).

ULIMIT(2) ULIMIT(2)

NAME

ulimit - get and set user limits

## **SYNOPSIS**

long ulimit (cmd, newlimit) int cmd; long newlimit;

## DESCRIPTION

This function provides for control over process limits. The cmd values available are:

- 1 Get the file size limit of the process. The limit is in units of 512-byte blocks and is inherited by child processes. Files of any size can be read.
- 2 Set the file size limit of the process to the value of *newlimit*. Any process may decrease this limit, but only a process with an effective user ID of super-user may increase the limit. *Ulimit* will fail and the limit will be unchanged if a process with an effective user ID other than super-user attempts to increase its file size limit. [EPERM]
- 3 Get the maximum possible break value. See brk(2).

## SEE ALSO

brk(2), write(2).

## DIAGNOSTICS

Upon successful completion, a non-negative value is returned. Otherwise, a value of -1 is returned and *errno* is set to indicate the error.

10/84 - 1 - 10/84

UMASK (2)

## NAME

umask - set and get file creation mask

## **SYNOPSIS**

int umask (cmask) int cmask;

## DESCRIPTION

Umask sets the process's file mode creation mask to cmask and returns the previous value of the mask. Only the low-order 9 bits of cmask and the file mode creation mask are used.

## SEE ALSO

chmod(2), creat(2), mknod(2), open(2). mkdir(1), sh(1) in the 3B2 Computer System User Reference Manual.

## DIAGNOSTICS

The previous value of the file mode creation mask is returned.

UMOUNT(2) UMOUNT(2)

NAME

umount - unmount a file system

## **SYNOPSIS**

int umount (spec) char \*spec;

## DESCRIPTION

Umount requests that a previously mounted file system contained on the block special device identified by spec be unmounted. Spec is a pointer to a path name. After unmounting the file system, the directory upon which the file system was mounted reverts to its ordinary interpretation.

Umount may be invoked only by the super-user.

Umount will fail if one or more of the following are true:

[EPERM]

The process's effective user ID is not super-user.

[ENXIO]

Spec does not exist.

[ENOTBLK]

Spec is not a block special device.

[EINVAL]

Spec is not mounted.

[EBUSY]

A file on spec is busy.

[EFAULT]

Spec points to an illegal address.

## SEE ALSO

mount(2).

## DIAGNOSTICS

Upon successful completion a value of 0 is returned. Otherwise, a value of -1 is returned and *errno* is set to indicate the error.

- 1 -

UNAME(2) UNAME(2)

## NAME

uname - get name of current UNIX system

## **SYNOPSIS**

```
#include <sys/utsname.h>
```

int uname (name)

struct utsname \*name;

#### DESCRIPTION

Uname stores information identifying the current UNIX system in the structure pointed to by name.

Uname uses the structure defined in <sys/utsname.h> whose members are:

char sysname[9]; char nodename[9]; char release[9]; char version[9]; char machine[9]:

Uname returns a null-terminated character string naming the current UNIX system in the character array sysname. Similarly, nodename contains the name that the system is known by on a communications network. Release and version further identify the operating system. Machine contains a standard name that identifies the hardware that the UNIX system is running on.

[EFAULT] Uname will fail if name points to an invalid address.

## SEE ALSO

uname(1) in the 3B2 Computer System User Reference Manual.

## DIAGNOSTICS

Upon successful completion, a non-negative value is returned. Otherwise, -1 is returned and *errno* is set to indicate the error.

10/84

-1-

UNLINK(2) UNLINK(2)

NAME

unlink - remove directory entry

## SYNOPSIS

int unlink (path) char \*path;

## DESCRIPTION

Unlink removes the directory entry named by the path name pointed to be path.

The named file is unlinked unless one or more of the following are true:

[ENOTDIR] A component of the path prefix is not a directory.

[ENOENT] The named file does not exist.

[EACCES] Search permission is denied for a component of the path

prefix

[EACCES] Write permission is denied on the directory containing the link

to be removed.

[EPERM] The named file is a directory and the effective user ID of the

process is not super-user.

[EBUSY] The entry to be unlinked is the mount point for a mounted file

system.

[ETXTBSY] The entry to be unlinked is the last link to a pure procedure

(shared text) file that is being executed.

[EROFS] The directory entry to be unlinked is part of a read-only file

system.

[EFAULT] Path points outside the process's allocated address space.

When all links to a file have been removed and no process has the file open, the space occupied by the file is freed and the file ceases to exist. If one or more processes have the file open when the last link is removed, the removal is post-poned until all references to the file have been closed.

## SEE ALSO

close(2), link(2), open(2).

rm(1) in the 3B2 Computer System User Reference Manual.

#### DIAGNOSTICS

Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned and *errno* is set to indicate the error.

USTAT(2) USTAT(2)

#### NAME

ustat - get file system statistics

## **SYNOPSIS**

```
#include <sys/types.h>
#include <ustat.h>
```

int ustat (dev, buf)

int dev;

struct ustat \*buf;

## DESCRIPTION

Ustat returns information about a mounted file system. Dev is a device number identifying a device containing a mounted file system. Buf is a pointer to a ustat structure that includes to following elements:

```
daddr_t f_tfree; /* Total free blocks */
ino_t f_tinode; /* Number of free inodes */
char f_fname[6]; /* Filsys name */
char f_fpack[6]; /* Filsys pack name */
```

Ustat will fail if one or more of the following are true:

[EINVAL]

Dev is not the device number of a device containing a

mounted file system.

[EFAULT]

Buf points outside the process's allocated address space.

#### SEE ALSO

stat(2), fs(4).

## DIAGNOSTICS

Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned and *errno* is set to indicate the error.

10/84

UTIME(2) UTIME(2)

#### NAME

utime - set file access and modification times

## SYNOPSIS

#include <sys/types.h>
int utime (path, times)
char \*path;
struct utimbuf \*times;

#### DESCRIPTION

Path points to a path name naming a file. Utime sets the access and modification times of the named file.

If *times* is NULL, the access and modification times of the file are set to the current time. A process must be the owner of the file or have write permission to use *utime* in this manner.

If times is not NULL, times is interpreted as a pointer to a utimbuf structure and the access and modification times are set to the values contained in the designated structure. Only the owner of the file or the super-user may use utime this way.

The times in the following structure are measured in seconds since 00:00:00 GMT, Jan. 1, 1970.

```
struct utimbuf {
    time_t actime; /* access time */
    time_t modtime; /* modification time */
};
```

Utime will fail if one or more of the following are true:

[ENOENT] The named file does not exist.

[ENOTDIR] A component of the path prefix is not a directory.

[EACCES] Search permission is denied by a component of the path

prefix.

[EPERM] The effective user ID is not super-user and not the owner of

the file and times is not NULL.

[EACCES] The effective user ID is not super-user and not the owner of

the file and times is NULL and write access is denied.

[EROFS] The file system containing the file is mounted read-only.

[EFAULT] Times is not NULL and points outside the process's allocated

address space.

[EFAULT] Path points outside the process's allocated address space.

## SEE ALSO

stat(2).

#### DIAGNOSTICS

Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned and *errno* is set to indicate the error.

WAIT(2) WAIT(2)

#### NAME

wait - wait for child process to stop or terminate

#### **SYNOPSIS**

int wait (stat\_loc)
int \*stat\_loc;
int wait ((int \*)0)

#### DESCRIPTION

Wait suspends the calling process until until one of the immediate children terminates or until a child that is being traced stops, because it has hit a break point. The wait system call will return prematurely if a signal is received and if a child process stopped or terminated prior to the call on wait, return is immediate.

If  $stat\_loc$  (taken as an integer) is non-zero, 16 bits of information called status are stored in the low order 16 bits of the location pointed to by  $stat\_loc$ . Status can be used to differentiate between stopped and terminated child processes and if the child process terminated, status identifies the cause of termination and passes useful information to the parent. This is accomplished in the following manner:

If the child process stopped, the high order 8 bits of status will contain the number of the signal that caused the process to stop and the low order 8 bits will be set equal to 0177.

If the child process terminated due to an exit call, the low order 8 bits of status will be zero and the high order 8 bits will contain the low order 8 bits of the argument that the child process passed to exit; see exit(2).

If the child process terminated due to a signal, the high order 8 bits of status will be zero and the low order 8 bits will contain the number of the signal that caused the termination. In addition, if the low order seventh bit (i.e., bit 200) is set, a "core image" will have been produced; see *signal* (2).

If a parent process terminates without waiting for its child processes to terminate, the parent process ID of each child process is set to 1. This means the initialization process inherits the child processes; see *intro*(2).

Wait will fail and return immediately if one or more of the following are true:

[ECHILD] The calling process has no existing unwaited-for child processes.

[EFAULT] Stat\_loc points to an illegal address.

## SEE ALSO

exec(2), exit(2), fork(2), intro(2), pause(2), ptrace(2), signal(2).

## WARNING

See WARNING in signal (2).

## DIAGNOSTICS

If wait returns due to the receipt of a signal, a value of -1 is returned to the calling process and *errno* is set to EINTR. If wait returns due to a stopped or terminated child process, the process ID of the child is returned to the calling process. Otherwise, a value of -1 is returned and *errno* is set to indicate the error.

WRITE(2) WRITE(2)

NAME

write - write on a file

**SYNOPSIS** 

int write (fildes, buf, nbyte)
int fildes;
char \*buf;
unsigned nbyte;

## DESCRIPTION

Fildes is a file descriptor obtained from a creat, open, dup, fcntl, or pipe system call

Write attempts to write nbyte bytes from the buffer pointed to by buf to the file associated with the fildes.

On devices capable of seeking, the actual writing of data proceeds from the position in the file indicated by the file pointer. Upon return from write, the file pointer is incremented by the number of bytes actually written.

On devices incapable of seeking, writing always takes place starting at the current position. The value of a file pointer associated with such a device is undefined.

If the O\_APPEND flag of the file status flags is set, the file pointer will be set to the end of the file prior to each write.

For regular files, if the O\_SYNC flag of the file status flags is set, the write will not return until both the file data and file status have been physically updated. This function is for special applications that require extra reliablity at the cost of performance. Also, for block special files, if this flag is set, the write will not return until the data has been physically updated.

Write will fail and the file pointer will remain unchanged if one or more of the following are true:

[EBADF]

Fildes is not a valid file descriptor open for writing.

[EPIPE and SIGPIPE signal]

An attempt is made to write to a pipe that is not open for reading by any process.

[EFBIG]

An attempt was made to write a file that exceeds the process's file size limit or the maximum file size. See *ulimit* (2).

[EFAULT]

Buf points outside the process's allocated address space.

[EINTR]

A signal was caught during the write system call.

If a write requests that more bytes be written than there is room for (e.g., the ulimit (see ulimit(2)) or the physical end of a medium), only as many bytes as there is room for will be written. For example, suppose there is space for 20 bytes more in a file before reaching a limit. A write of 512-bytes will return 20. The next write of a non-zero number of bytes will give a failure return (except as noted below).

If the file being written is a pipe (or FIFO) and the O\_NDELAY flag of the file flag word is set, then write to a full pipe (or FIFO) will return a count of 0. Otherwise (O\_NDELAY clear), writes to a full pipe (or FIFO) will block until space becomes available.

## **SEE ALSO**

creat(2), dup(2), fcntl(2), lseek(2), open(2), pipe(2), ulimit(2).

# DIAGNOSTICS

Upon successful completion the number of bytes actually written is returned. Otherwise, -1 is returned and *errno* is set to indicate the error.

INTRO(3)

NAME

intro - introduction to subroutines and libraries

SYNOPSIS

#include <stdio.h>
#include <math.h>

#### DESCRIPTION

This section describes functions found in various libraries, other than those functions that directly invoke UNIX system primitives, which are described in Section 2 of this volume. Certain major collections are identified by a letter after the section number:

- (3C) These functions, together with those of Section 2 and those marked (3S), constitute the Standard C Library libc, which is automatically loaded by the C compiler, cc(1). The link editor ld(1) searches this library under the -lc option. Declarations for some of these functions may be obtained from #include files indicated on the appropriate pages.
- (3S) These functions constitute the "standard I/O package" (see *stdio*(3S)). These functions are in the library *libc*, already mentioned. Declarations for these functions may be obtained from the #include file <stdio.h>.
- (3M) These functions constitute the Math Library, libm. They are automatically loaded as needed by the FORTRAN compiler f77(1). They are not automatically loaded by the C compiler, cc(1); however, the link editor searches this library under the -lm option. Declarations for these functions may be obtained from the #include file <math.h>. Several generally useful mathematical constants are also defined there (see math (5)).
- (3X) Various specialized libraries. The files in which these libraries are found are given on the appropriate pages.
- (3F) These functions constitute the FORTRAN intrinsic function library, *libF77*. These functions are automatically available to the FORTRAN programmer and require no special invocation of the compiler.

## **DEFINITIONS**

A character is any bit pattern able to fit into a byte on the machine. The null character is a character with value 0, represented in the C language as '\0'. A character array is a sequence of characters. A null-terminated character array is a sequence of characters, the last of which is the null character. A string is a designation for a null-terminated character array. The null string is a character array containing only the null character. A NULL pointer is the value that is obtained by casting 0 into a pointer. The C language guarantees that this value will not match that of any legitimate pointer, so many functions that return pointers return it to indicate an error. NULL is defined as 0 in <stdio.h>; the user can include an appropriate definition if not using <stdio.h>

Many groups of FORTRAN intrinsic functions have *generic* function names that do not require explicit or implicit type declaration. The type of the function will be determined by the type of its argument(s). For example, the generic function max will return an integer value if given integer arguments (max0), a real value if given real arguments (amax1), or a double-precision value if given double-precision arguments (amax1).

#### FILES

/lib/libc.a /lib/libm.a /usr/lib/libF77.a INTRO(3) INTRO(3)

#### SEE ALSO

intro(2), stdio(3S), math(5).

ar(1), ld(1), nm(1) in the 3B2 Computer Software Generation System Utili-

cc(1), lint(1) in the 3B2 Computer C Programming Language Utilities. f77(1) in the 3B2 Computer FORTRAN Programming Language Utilities.

#### DIAGNOSTICS

Functions in the C and Math Libraries (3C and 3M) may return the conventional values 0 or  $\pm HUGE$  (the largest-magnitude single-precision floating-point numbers; HUGE is defined in the < math.h > header file) when the function is undefined for the given arguments or when the value is not representable. In these cases, the external variable errno (see intro(2)) is set to the value EDOM or ERANGE. As many of the FORTRAN intrinsic functions use the routines found in the Math Library, the same conventions apply.

## WARNING

Many of the functions in the libraries call and/or refer to other functions and external variables described in this section and in section 2 (System Calls). If a program inadvertantly defines a function or external variable with the same name, the presumed library version of the function or external variable may not be loaded. The lint(1) program checker reports name conflicts of this kind as "multiple declarations" of the names in question. Definitions for sections 2, 3C, and 3S are checked automatically. Other definitions can be included by using the -1 option (for example, -1m includes definitions for the Math Library, section 3M). Use of lint is highly recommended.

a64l, 164a - convert between long integer and base-64 ASCII string

## SYNOPSIS

long a641 (s) char \*s; char \*164a (l) long l;

## DESCRIPTION

These functions are used to maintain numbers stored in *base-64* ASCII characters. This is a notation by which long integers can be represented by up to six characters; each character represents a "digit" in a radix-64 notation.

The characters used to represent "digits" are  $\cdot$  for 0, / for 1, 0 through 9 for 2-11, A through  $\mathbb{Z}$  for 12-37, and a through  $\mathbb{Z}$  for 38-63.

A641 takes a pointer to a null-terminated base-64 representation and returns a corresponding **long** value. If the string pointed to by s contains more than six characters, a641 will use the first six.

L64a takes a long argument and returns a pointer to the corresponding base-64 representation. If the argument is 0, 164a returns a pointer to a null string.

## **BUGS**

The value returned by 164a is a pointer into a static buffer, the contents of which are overwritten by each call.

abort - generate an IOT fault

#### SYNOPSIS

int abort ()

## **DESCRIPTION**

Abort first closes all open files if possible, then causes an IOT signal to be sent to the process. This usually results in termination with a core dump.

It is possible for *abort* to return control if SIGIOT is caught or ignored, in which case the value returned is that of the *kill*(2) system call.

## **SEE ALSO**

exit(2), kill(2), signal(2).

sdb(1) in the 3B2 Computer Extended Software Generation System Utilities.

## DIAGNOSTICS

If SIGIOT is neither caught nor ignored, and the current directory is writable, a core dump is produced and the message "abort — core dumped" is written by the shell.

abs – return integer absolute value

SYNOPSIS

int abs (i)

int i;

**DESCRIPTION** 

Abs returns the absolute value of its integer operand.

SEE ALSO

floor(3M).

**BUGS** 

In two's-complement representation, the absolute value of the negative integer with largest magnitude is undefined. Some implementations trap this error, but others simply ignore it.

bsearch - binary search a sorted table

#include <stdio.h>

## **SYNOPSIS**

```
#include <search.h>
```

char \*bsearch ((char \*) key, (char \*) base, nel, sizeof (\*key), compar)
unsigned nel;
int (\*compar)( );

## DESCRIPTION

Bsearch is a binary search routine generalized from Knuth (6.2.1) Algorithm B. It returns a pointer into a table indicating where a datum may be found. The table must be previously sorted in increasing order according to a provided comparison function. Key points to a datum instance to be sought in the table. Base points to the element at the base of the table. Nel is the number of elements in the table. Compar is the name of the comparison function, which is called with two arguments that point to the elements being compared. The function must return an integer less than, equal to, or greater than zero as accordinly the first argument is to be considered less than, equal to, or greater than the second.

## **EXAMPLE**

The example below searches a table containing pointers to nodes consisting of a string and its length. The table is ordered alphabetically on the string in the node pointed to by each entry.

This code fragment reads in strings and either finds the corresponding node and prints out the string and its length, or prints an error message.

```
#include <search.h>
#define TABSIZE
                       1000
struct node {
                               /* these are stored in the table */
       char *string;
       int length;
struct node table[TABSIZE];
                               /* table to be searched */
{
       struct node *node ptr, node;
       int node_compare(); /* routine to compare 2 nodes */
       char str space[20]; /* space to read string into */
       node.string = str space;
       while (scanf("%s", node.string) != EOF) {
               node ptr = (struct node *)bsearch((char *)(&node),
                           (char *)table, TABSIZE,
                           sizeof(struct node), node_compare);
               if (node ptr != NULL) {
                       (void) printf("string = \%20s, length = \%d\n",
                               node ptr->string, node ptr->length);
               } else {
                        (void) printf("not found: %s\n", node.string);
```

```
}

/*

This routine compares two nodes based on an alphabetical ordering of the string field.

*/
int
node_compare(node1, node2)
struct node *node1, *node2;
{
    return strcmp(node1->string, node2->string);
}
```

## **NOTES**

The pointers to the key and the element at the base of the table should be of type pointer-to-element, and cast to type pointer-to-character.

The comparison function need not compare every byte, so arbitrary data may be contained in the elements in addition to the values being compared. Although declared as type pointer-to-character, the value returned should be

cast into type pointer-to-element.

## SEE ALSO

hsearch(3C), lsearch(3C), qsort(3C), tsearch(3C).

# DIAGNOSTICS

A NULL pointer is returned if the key cannot be found in the table.

clock - report CPU time used

## **SYNOPSIS**

long clock ()

## **DESCRIPTION**

Clock returns the amount of CPU time (in microseconds) used since the first call to clock. The time reported is the sum of the user and system times of the calling process and its terminated child processes for which it has executed wait (2) or system (3S).

The resolution of the clock is 10 milliseconds on AT&T Technologies 3B computer processors.

## SEE ALSO

times(2), wait(2), system(3S).

## BUGS

The value returned by *clock* is defined in microseconds for compatibility with systems that have CPU clocks with much higher resolution. Because of this, the value returned will wrap around after accumulating only 2147 seconds of CPU time (about 36 minutes).

```
NAME
```

toupper, tolower, \_toupper, \_tolower, toascii - translate characters

# SYNOPSIS

#include <ctype.h>

int toupper (c)

int c;

int tolower (c)

int c;

int \_toupper (c)

int c;

int \_tolower (c)

int c;

int toascii (c)

int c;

## DESCRIPTION

Toupper and tolower have as domain the range of getc(3S): the integers from -1 through 255. If the argument of toupper represents a lower-case letter, the result is the corresponding upper-case letter. If the argument of tolower represents an upper-case letter, the result is the corresponding lower-case letter. All other arguments in the domain are returned unchanged.

The macros \_toupper and \_tolower, are macros that accomplish the same thing as toupper and tolower but have restricted domains and are faster. \_toupper requires a lower-case letter as its argument; its result is the corresponding upper-case letter. The macro \_tolower requires an upper-case letter as its argument; its result is the corresponding lower-case letter. Arguments outside the domain cause undefined results.

Toascii yields its argument with all bits turned off that are not part of a standard ASCII character; it is intended for compatibility with other systems.

- 1 -

#### SEE ALSO

ctype(3C), getc(3S).

crypt, setkey, encrypt - generate hashing encryption

#### **SYNOPSIS**

```
char *crypt (key, salt)
char *key, *salt;
void setkey (key)
char *key;
void encrypt (block, fake)
char *block;
int fake;
```

## DESCRIPTION

Crypt is the password encryption function. It is based on a one way hashing encryption algorithm with variations intended (among other things) to frustrate use of hardware implementations of a key search.

Key is a user's typed password. Salt is a two-character string chosen from the set [a-zA-Z0-9./]; this string is used to perturb the hashing algorithm in one of 4096 different ways, after which the password is used as the key to encrypt repeatedly a constant string. The returned value points to the encrypted password. The first two characters are the salt itself.

The setkey and encrypt entries provide (rather primitive) access to the actual hashing algorithm. The argument of setkey is a character array of length 64 containing only the characters with numerical value 0 and 1. If this string is divided into groups of 8, the low-order bit in each group is ignored; this gives a 56-bit key which is set into the machine. This is the key that will be used with the hashing algorithm to encrypt the string block with the function encrypt.

The argument to the *encrypt* entry is a character array of length 64 containing only the characters with numerical value 0 and 1. The argument array is modified in place to a similar array representing the bits of the argument after having been subjected to the hashing algorithm using the key set by *setkey*. Fake is not used and is ignored, but should be present if *lint* (1) is used.

#### SEE ALSO

getpass(3C), passwd(4).

login(1), passwd(1) in the 3B2 Computer System User Reference Manual.

## BUGS

The return value points to static data that are overwritten by each call.

ctermid - generate file name for terminal

# SYNOPSIS

#include <stdio.h>
char \*ctermid (s)
char \*s;

## DESCRIPTION

Ctermid generates the path name of the controlling terminal for the current process, and stores it in a string.

If s is a NULL pointer, the string is stored in an internal static area, the contents of which are overwritten at the next call to *ctermid*, and the address of which is returned. Otherwise, s is assumed to point to a character array of at least **L\_ctermid** elements; the path name is placed in this array and the value of s is returned. The constant **L\_ctermid** is defined in the < stdio.h> header file.

#### NOTES

The difference between ctermid and ttyname (3C) is that ttyname must be handed a file descriptor and returns the actual name of the terminal associated with that file descriptor, while ctermid returns a string (/dev/tty) that will refer to the terminal if used as a file name. Thus ttyname is useful only if the process already has at least one file open to a terminal.

## SEE ALSO

ttyname(3C).

ctime, localtime, gmtime, asctime, tzset - convert date and time to string

## **SYNOPSIS**

```
#include <time.h>
char *ctime (clock)
long *clock;
struct tm *localtime (clock)
long *clock;
struct tm *gmtime (clock)
long *clock;
char *asctime (tm)
struct tm *tm;
extern long timezone;
extern int daylight;
extern char *tzname[2];
void tzset ( )
```

## DESCRIPTION

Ctime converts a long integer, pointed to by clock, representing the time in seconds since 00:00:00 GMT, January 1, 1970, and returns a pointer to a 26-character string in the following form. All the fields have constant width.

```
Sun Sep 16 01:03:52 1973\n\0
```

Localtime and gmtime return pointers to "tm" structures, described below. Localtime corrects for the time zone and possible Daylight Savings Time; gmtime converts directly to Greenwich Mean Time (GMT), which is the time the UNIX system uses.

Asctime converts a "tm" structure to a 26-character string, as shown in the above example, and returns a pointer to the string.

Declarations of all the functions and externals, and the "tm" structure, are in the <time.h> header file. The structure declaration is:

```
struct tm {
                        /* seconds (0 - 59) */
      int tm sec;
      int tm min;
                        /* minutes (0 - 59) */
                        /* hours (0 - 23) */
      int tm hour;
                        /* day of month (1 - 31) */
      int tm mday;
      int tm mon;
                                /* month of year (0 - 11) */
                        /* year - 1900 */
      int tm year;
      int tm wday;
                        /* day of week (Sunday = 0) */
      int tm yday;
                        /* day of year (0 - 365) */
      int tm_isdst;
}:
```

Tm isdst is non-zero if Daylight Savings Time is in effect.

The external long variable timezone contains the difference, in seconds, between GMT and local standard time (in EST, timezone is 5\*60\*60); the external variable daylight is non-zero if and only if the standard U.S.A. Daylight Savings Time conversion should be applied. The program knows about the peculiarities of this conversion in 1974 and 1975; if necessary, a table for these years can be extended.

If an environment variable named TZ is present, asctime uses the contents of the variable to override the default time zone. The value of TZ must be a

CTIME (3C)

three-letter time zone name, followed by a number representing the difference between local time and Greenwich Mean Time in hours, followed by an optional three-letter name for a daylight time zone. For example, the setting for New Jersey would be EST5EDT. The effects of setting TZ are thus to change the values of the external variables timezone and daylight; in addition, the time zone names contained in the external variable

# char \*tzname[2] = { "EST", "EDT" };

are set from the environment variable TZ. The function *tzset* sets these external variables from TZ; *tzset* is called by *asctime* and may also be called explicitly by the user.

Note that in most installations, TZ is set by default when the user logs on, to a value in the local /etc/profile file (see profile(4)).

## SEE ALSO

time(2), getenv(3C), profile(4), environ(5).

## **BUGS**

The return values point to static data whose content is overwritten by each call.

isalpha, isupper, islower, isdigit, isxdigit, isalnum, isspace, ispunct, isprint, isgraph, iscntrl, isascii — classify characters

## **SYNOPSIS**

#include <ctype.h>
int isalpha (c)
int c;

## DESCRIPTION

These macros classify character-coded integer values by table lookup. Each is a predicate returning nonzero for true, zero for false. *Isascii* is defined on all integer values; the rest are defined only where *isascii* is true and on the single non-ASCII value EOF  $(-1 - \sec stdio(3S))$ .

isalpha c is a letter.

isupper c is an upper-case letter.
 islower c is a lower-case letter.
 isdigit c is a digit [0-9].

isxdigit c is a hexadecimal digit [0-9], [A-F] or [a-f].

isalnum c is an alphanumeric (letter or digit).

isspace c is a space, tab, carriage return, new-line, vertical tab, or

form-feed.

ispunct c is a punctuation character (neither control nor

alphanumeric).

isprint c is a printing character, code 040 (space) through 0176

(tilde).

isgraph c is a printing character, like isprint except false for space.

iscntrl c is a delete character (0177) or an ordinary control character

(less than 040).

isascii c is an ASCII character, code less than 0200.

## SEE ALSO

stdio(3S), ascii(5).

## DIAGNOSTICS

If the argument to any of these macros is not in the domain of the function, the result is undefined.

cuserid - get character login name of the user

## SYNOPSIS

#include <stdio.h>

char \*cuserid (s)

char \*s;

## DESCRIPTION

Cuserid generates a character-string representation of the login name that the owner of the current process is logged in under. If s is a NULL pointer, this representation is generated in an internal static area, the address of which is returned. Otherwise, s is assumed to point to an array of at least L\_cuserid characters; the representation is left in this array. The constant L\_cuserid is defined in the <stdio.h> header file.

# DIAGNOSTICS

If the login name cannot be found, cuserid returns a NULL pointer; if s is not a NULL pointer, a null character ( $\setminus 0$ ) will be placed at s[0].

## SEE ALSO

getlogin(3C), getpwent(3C).

dial - establish an out-going terminal line connection

#### **SYNOPSIS**

```
#include < dial.h>
int dial (call)
CALL call;
void undial (fd)
int fd;
```

## DESCRIPTION

Dial returns a file-descriptor for a terminal line open for read/write. The argument to dial is a CALL structure (defined in the < dial.h> header file).

When finished with the terminal line, the calling program must invoke *undial* to release the semaphore that has been set during the allocation of the terminal device.

The definition of CALL in the  $\langle dial.h \rangle$  header file is:

```
typedef struct {
         struct termio *attr;
                                     /* pointer to termio attribute struct */
                                     /* transmission data rate */
         int
                        baud:
                                     /* 212A modem: low=300, high=1200 */
                        speed:
         int
                                     /* device name for out-going line */
         char
                        *line;
                        *telno;
                                     /* pointer to tel-no digits string */
         char
                                     /* specify modem control for direct lines */
         int
                        modem;
                                     /*Will hold the name of the device used
         char
                        *device;
                                     to make a connection */
                        dev len;
                                     /* The length of the device used to make
         int
                                     connection */
```

## } CALL;

The CALL element *speed* is intended only for use with an outgoing dialed call, in which case its value should be either 300 or 1200 to identify the 113A modem, or the high- or low-speed setting on the 212A modem. Note that the 113A modem or the low-speed setting of the 212A modem will transmit at any rate between 0 and 300 bits per second. However, the high-speed setting of the 212A modem transmits and receivers at 1200 bits per secound only. The CALL element *baud* is for the desired transmission baud rate. For example, one might set *baud* to 110 and *speed* to 300 (or 1200). However, if **speed** set to 1200 baud must be set to high (1200).

If the desired terminal line is a direct line, a string pointer to its device-name should be placed in the line element in the CALL structure. Legal values for such terminal device names are kept in the L-devices file. In this case, the value of the baud element need not be specified as it will be determined from the L-devices file.

The telno element is for a pointer to a character string representing the telephone number to be dialed. Such numbers may consist only of symbols described on the acu(7). The termination symbol will be supplied by the dial function, and should not be included in the telno string passed to dial in the CALL structure.

The CALL element *modem* is used to specify modem control for direct lines. This element should be non-zero if modem control is required. The CALL element *attr* is a pointer to a *termio* structure, as defined in the *termio.h* header file. A NULL value for this pointer element may be passed to the *dial* function, but if such a structure is included, the elements specified in it will be set for the outgoing terminal line before the connection is established. This is often important for certain attributes such as parity and baud-rate.

The CALL element device is used to hold the device name (cul..) that establishes the connection.

The CALL element dev\_len is the length of the device name that is copied into the array device.

# WARNINGS

Including the <dial.h> header file automatically includes the <termio.h> header file.

The above routine uses <stdio.h>, which causes it to increase the size of programs, not otherwise using standard I/O, more than might be expected.

#### BUGS

An alarm(2) system call for 3600 seconds is made (and caught) within the dial module for the purpose of "touching" the LCK.. file and constitutes the device allocation semaphore for the terminal device. Otherwise, uucp (1C) may simply delete the LCK.. entry on its 90-minute clean-up rounds. The alarm may go off while the user program is in a read(2) or write(2) system call, causing an apparent error return. If the user program expects to be around for an hour or more, error returns from reads should be checked for (errno = = EINTR), and the read possibly reissued.

drand48, erand48, lrand48, nrand48, mrand48, jrand48, srand48, seed48, lcong48 — generate uniformly distributed pseudo-random numbers

## SYNOPSIS

double drand48 ( )

double erand48 (xsubi) unsigned short xsubi[3];

long lrand48 ()

long nrand48 (xsubi) unsigned short xsubi[3];

long mrand48 ()

long jrand48 (xsubi) unsigned short xsubi[3];

void srand48 (seedval) long seedval:

unsigned short \*seed48 (seed16v) unsigned short seed16v[3];

void lcong48 (param)
unsigned short param[7];

## DESCRIPTION

This family of functions generates pseudo-random numbers using the well-known linear congruential algorithm and 48-bit integer arithmetic.

Functions drand48 and erand48 return non-negative double-precision floating-point values uniformly distributed over the interval [0.0, 1.0).

Functions lrand48 and nrand48 return non-negative long integers uniformly distributed over the interval  $[0, 2^{31})$ .

Functions mrand48 and jrand48 return signed long integers uniformly distributed over the interval  $[-2^{31}, 2^{31})$ .

Functions srand48, seed48 and lcong48 are initialization entry points, one of which should be invoked before either drand48, lrand48 or mrand48 is called. (Although it is not recommended practice, constant default initializer values will be supplied automatically if drand48, lrand48 or mrand48 is called without a prior call to an initialization entry point.) Functions erand48, nrand48 and jrand48 do not require an initialization entry point to be called first.

All the routines work by generating a sequence of 48-bit integer values,  $X_i$ , according to the linear congruential formula

$$X_{n+1} = (aX_n + c)_{\text{mod } m} \qquad n \geqslant 0.$$

The parameter  $m=2^{48}$ ; hence 48-bit integer arithmetic is performed. Unless *lcong48* has been invoked, the multiplier value a and the addend value c are given by

$$a = 5DEECE66D_{16} = 273673163155_8$$
  
 $c = B_{16} = 13_8$ .

The value returned by any of the functions drand48, erand48, lrand48, nrand48, mrand48 or jrand48 is computed by first generating the next 48-bit  $X_i$  in the sequence. Then the appropriate number of bits, according to the type of data item to be returned, are copied from the high-order (leftmost) bits of  $X_i$  and transformed into the returned value.

The functions drand48, lrand48 and mrand48 store the last 48-bit  $X_i$  generated in an internal buffer; that is why they must be initialized prior to being invoked. The functions erand48, nrand48 and jrand48 require the calling program to provide storage for the successive  $X_i$  values in the array specified as an argument when the functions are invoked. That is why these routines do not have to be initialized; the calling program merely has to place the desired initial value of  $X_i$  into the array and pass it as an argument. By using different arguments, functions erand48, nrand48 and jrand48 allow separate modules of a large program to generate several independent streams of pseudo-random numbers, i.e., the sequence of numbers in each stream will not depend upon how many times the routines have been called to generate numbers for the other streams

The initializer function *srand48* sets the high-order 32 bits of  $X_i$  to the 32 bits contained in its argument. The low-order 16 bits of  $X_i$  are set to the arbitrary value  $330E_{16}$ .

The initializer function seed48 sets the value of  $X_i$  to the 48-bit value specified in the argument array. In addition, the previous value of  $X_i$  is copied into a 48-bit internal buffer, used only by seed48, and a pointer to this buffer is the value returned by seed48. This returned pointer, which can just be ignored if not needed, is useful if a program is to be restarted from a given point at some future time — use the pointer to get at and store the last  $X_i$  value, and then use this value to reinitialize via seed48 when the program is restarted.

The initialization function lcong48 allows the user to specify the initial  $X_i$ , the multiplier value a, and the addend value c. Argument array elements param[0-2] specify  $X_i$ , param[3-5] specify the multiplier a, and param[6] specifies the 16-bit addend c. After lcong48 has been called, a subsequent call to either srand48 or seed48 will restore the "standard" multiplier and addend values, a and c, specified on the previous page.

#### NOTES

The routines are coded in portable C. The source code for the portable version can even be used on computers which do not have floating-point arithmetic. In such a situation, functions *drand48* and *erand48* do not exist; instead, they are replaced by the two new functions below.

long irand48 (m) unsigned short m;

long krand48 (xsubi, m) unsigned short xsubi[3], m;

Functions *irand48* and *krand48* return non-negative long integers uniformly distributed over the interval [0, m-1].

## SEE ALSO

rand(3C).

ecvt, fcvt, gcvt - convert floating-point number to string

# SYNOPSIS

char \*ecvt (value, ndigit, decpt, sign)
double value;
int ndigit, \*decpt, \*sign;
char \*fcvt (value, ndigit, decpt, sign)
double value;
int ndigit, \*decpt, \*sign;
char \*gcvt (value, ndigit, buf)
double value;
int ndigit;
char \*buf;

# DESCRIPTION

Ecvt converts value to a null-terminated string of ndigit digits and returns a pointer thereto. The high-order digit is non-zero, unless the value is zero. The low-order digit is rounded. The position of the decimal point relative to the beginning of the string is stored indirectly through decpt (negative means to the left of the returned digits). The decimal point is not included in the returned string. If the sign of the result is negative, the word pointed to by sign is non-zero, otherwise it is zero.

Fcvt is identical to ecvt, except that the correct digit has been rounded for printf "%f" (FORTRAN F-format) output of the number of digits specified by ndigit.

Gcvt converts the value to a null-terminated string in the array pointed to by buf and returns buf. It attempts to produce ndigit significant digits in FORTRAN F-format if possible, otherwise E-format, ready for printing. A minus sign, if there is one, or a decimal point will be included as part of the returned string. Trailing zeros are suppressed.

# SEE ALSO

printf(3S).

## **BUGS**

The values returned by ecvt and fcvt point to a single static data array whose content is overwritten by each call.

end, etext, edata - last locations in program

## **SYNOPSIS**

extern end; extern etext; extern edata;

## **DESCRIPTION**

These names refer neither to routines nor to locations with interesting contents. The address of *etext* is the first address above the program text, *edata* above the initialized data region, and *end* above the uninitialized data region.

When execution begins, the program break (the first location beyond the data) coincides with end, but the program break may be reset by the routines of brk(2), malloc(3C), standard input/output (stdio(3S)), the profile (-p) option of cc(1), and so on. Thus, the current value of the program break should be determined by sbrk(0) (see brk(2)).

#### SEE ALSO

brk(2), malloc(3C), stdio(3S). cc(1) in the 3B2 Computer C Programming Language Utilities.

fclose, fflush - close or flush a stream

## **SYNOPSIS**

#include <stdio.h>

int fclose (stream)

FILE \*stream;

int fflush (stream)

FILE \*stream;

## DESCRIPTION

Fclose causes any buffered data for the named stream to be written out, and the stream to be closed.

Fclose is performed automatically for all open files upon calling exit (2).

Fflush causes any buffered data for the named stream to be written to that file. The stream remains open.

## SEE ALSO

close(2), exit(2), fopen(3S), setbuf(3S).

# DIAGNOSTICS

These functions return 0 for success, and EOF if any error (such as trying to write to a file that has not been opened for writing) was detected.

ferror, feof, clearerr, fileno - stream status inquiries

## **SYNOPSIS**

#include <stdio.h>

int ferror (stream)

FILE \*stream;

int feof (stream)

FILE \*stream:

void clearerr (stream)

FILE \*stream:

int fileno (stream)

FILE \*stream;

# **DESCRIPTION**

Ferror returns non-zero when an I/O error has previously occurred reading from or writing to the named stream, otherwise zero.

Feof returns non-zero when EOF has previously been detected reading the named input stream, otherwise zero.

Clearerr resets the error indicator and EOF indicator to zero on the named stream.

Fileno returns the integer file descriptor associated with the named stream; see open(2).

# **NOTES**

All these functions are implemented as macros; they cannot be declared or redeclared.

# SEE ALSO

open(2), fopen(3S).

fopen, freopen, fdopen - open a stream

## **SYNOPSIS**

#include <stdio.h>

FILE \*fopen (file-name, type)

char \*file-name, \*type;

FILE \*freopen (file-name, type, stream)

char \*file-name, \*type;

FILE \*stream;

FILE \*fdopen (fildes, type)

int fildes;

char \*type;

#### DESCRIPTION

Fopen opens the file named by file-name and associates a stream with it. Fopen returns a pointer to the FILE structure associated with the stream.

File-name points to a character string that contains the name of the file to be opened.

Type is a character string having one of the following values:

"r" open for reading

"w" truncate or create for writing

"a" append; open for writing at end of file, or create for writing

"r+" open for update (reading and writing)

"w+" truncate or create for update

"a+" append; open or create for update at end-of-file

Freopen substitutes the named file in place of the open stream. The original stream is closed, regardless of whether the open ultimately succeeds. Freopen returns a pointer to the FILE structure associated with stream.

Freopen is typically used to attach the preopened streams associated with stdin, stdout and stderr to other files.

Fdopen associates a stream with a file descriptor. File descriptors are obtained from open, dup, creat, or pipe (2), which open files but do not return pointers to a FILE structure stream. Streams are necessary input for many of the Section 3S library routines. The type of stream must agree with the mode of the open file.

When a file is opened for update, both input and output may be done on the resulting *stream*. However, output may not be directly followed by input without an intervening *fseek* or *rewind*, and input may not be directly followed by output without an intervening *fseek*, *rewind*, or an input operation which encounters end-of-file.

When a file is opened for append (i.e., when type is "a" or "a+"), it is impossible to overwrite information already in the file. Fseek may be used to reposition the file pointer to any position in the file, but when output is written to the file, the current file pointer is disregarded. All output is written at the end of the file and causes the file pointer to be repositioned at the end of the output. If two separate processes open the same file for append, each process may write freely to the file without fear of destroying output being written by the other. The output from the two processes will be intermixed in the file in the order in which it is written.

FOPEN(3S)

SEE ALSO

creat(2), dup(2), open(2), pipe(2), fclose(3S), fseek(3S).

DIAGNOSTICS

Fopen and freopen return a NULL pointer on failure.

fread, fwrite - binary input/output

## SYNOPSIS

#include <stdio.h>

int fread (ptr, size, nitems, stream) char \*ptr; int size, nitems; FILE \*stream; int fwrite (ptr size nitems stream)

int fwrite (ptr, size, nitems, stream) char \*ptr; int size, nitems; FILE \*stream;

#### DESCRIPTION

Fread copies, into an array pointed to by ptr, nitems items of data from the named input stream, where an item of data is a sequence of bytes (not necessarily terminated by a null byte) of length size. Fread stops appending bytes if an end-of-file or error condition is encountered while reading stream, or if nitems items have been read. Fread leaves the file pointer in stream, if defined, pointing to the byte following the last byte read if there is one. Fread does not change the contents of stream.

Fwrite appends at most nitems items of data from the array pointed to by ptr to the named output stream. Fwrite stops appending when it has appended nitems items of data or if an error condition is encountered on stream. Fwrite does not change the contents of the array pointed to by ptr.

The argument size is typically size of (\*ptr) where the pseudo-function size of specifies the length of an item pointed to by ptr. If ptr points to a data type other than char it should be cast into a pointer to char.

## SEE ALSO

read(2), write(2), fopen(3S), getc(3S), gets(3S), printf(3S), putc(3S), puts(3S), scanf(3S).

## DIAGNOSTICS

Fread and fwrite return the number of items read or written. If size or nitems is non-positive, no characters are read or written and 0 is returned by both fread and fwrite.

frexp, ldexp, modf - manipulate parts of floating-point numbers

# **SYNOPSIS**

double frexp (value, eptr)
double value;
int \*eptr;
double ldexp (value, exp)
double value;
int exp;
double modf (value, iptr)
double value, \*iptr;

# DESCRIPTION

Every non-zero number can be written uniquely as  $x*2^n$ , where the "mantissa" (fraction) x is in the range  $0.5 \le |x| < 1.0$ , and the "exponent" n is an integer. Frexp returns the mantissa of a double value, and stores the exponent indirectly in the location pointed to by eptr. If value is zero, both results returned by frexp are zero.

Ldexp returns the quantity value \* 2 exp.

Modf returns the signed fractional part of value and stores the integral part indirectly in the location pointed to by iptr.

## DIAGNOSTICS

If *ldexp* would cause overflow, ±HUGE is returned (according to the sign of *value*), and *errno* is set to ERANGE.

If *ldexp* would cause underflow, zero is returned and *errno* is set to ERANGE.

fseek, rewind, ftell - reposition a file pointer in a stream

## **SYNOPSIS**

#include <stdio.h>

int fseek (stream, offset, ptrname)

FILE \*stream;

long offset:

int ptrname;

void rewind (stream)

FILE \*stream:

long ftell (stream)

FILE \*stream;

## DESCRIPTION

Fseek sets the position of the next input or output operation on the stream. The new position is at the signed distance offset bytes from the beginning, from the current position, or from the end of the file, according as ptrname has the value 0, 1, or 2.

Rewind (stream) is equivalent to fseek (stream, 0L, 0), except that no value is returned.

Fseek and rewind undo any effects of ungetc (3S).

After *fseek* or *rewind*, the next operation on a file opened for update may be either input or output.

Ftell returns the offset of the current byte relative to the beginning of the file associated with the named stream.

#### SEE ALSO

lseek(2), fopen(3S), popen(3S), ungetc(3S).

## DIAGNOSTICS

Fseek returns non-zero for improper seeks, otherwise zero. An improper seek can be, for example, an fseek done on a file that has not been opened via fopen; in particular, fseek may not be used on a terminal, or on a file opened via popen(3S).

## WARNING

Although on the UNIX system an offset returned by *ftell* is measured in bytes, and it is permissible to seek to positions relative to that offset, portability to non-UNIX systems requires that an offset be used by *fseek* directly. Arithmetic may not meaningfully be performed on such an offset, which is not necessarily measured in bytes.

ftw - walk a file tree

**SYNOPSIS** 

#include <ftw.h>

int ftw (path, fn, depth)
char \*path;
int (\*fn) ( );
int depth;

## DESCRIPTION

Ftw recursively descends the directory hierarchy rooted in path. For each object in the hierarchy, ftw calls fn, passing it a pointer to a null-terminated character string containing the name of the object, a pointer to a stat structure (see stat(2)) containing information about the object, and an integer. Possible values of the integer, defined in the <ftw.h> header file, are FTW\_F for a file, FTW\_D for a directory, FTW\_DNR for a directory that cannot be read, and FTW\_NS for an object for which stat could not successfully be executed. If the integer is FTW\_DNR, descendants of that directory will not be processed. If the integer is FTW\_NS, the stat structure will contain garbage. An example of an object that would cause FTW\_NS to be passed to fn would be a file in a directory with read but without execute (search) permission.

Ftw visits a directory before visiting any of its descendants.

The tree traversal continues until the tree is exhausted, an invocation of fn returns a nonzero value, or some error is detected within ftw (such as an I/O error). If the tree is exhausted, ftw returns zero. If fn returns a nonzero value, ftw stops its tree traversal and returns whatever value was returned by fn. If ftw detects an error, it returns -1, and sets the error type in errno.

Ftw uses one file descriptor for each level in the tree. The depth argument limits the number of file descriptors so used. If depth is zero or negative, the effect is the same as if it were 1. Depth must not be greater than the number of file descriptors currently available for use. Ftw will run more quickly if depth is at least as large as the number of levels in the tree.

### SEE ALSO

stat(2), malloc(3C).

# BUGS

Because ftw is recursive, it is possible for it to terminate with a memory fault when applied to very deep file structures.

It could be made to run faster and use less storage on deep structures at the cost of considerable complexity.

Ftw uses malloc(3C) to allocate dynamic storage during its operation. If ftw is forcibly terminated, such as by longjmp being executed by fn or an interrupt routine, ftw will not have a chance to free that storage, so it will remain permanently allocated. A safe way to handle interrupts is to store the fact that an interrupt has occurred, and arrange to have fn return a nonzero value at its next invocation.

getc, getchar, fgetc, getw - get character or word from a stream

## SYNOPSIS

#include <stdio.h>

int getc (stream)

FILE \*stream;

int getchar ()

int fgetc (stream)

FILE \*stream;

int getw (stream)

FILE \*stream;

#### DESCRIPTION

Getc returns the next character (i.e., byte) from the named input stream, as an integer. It also moves the file pointer, if defined, ahead one character in stream. Getchar is defined as getc(stdin). Getc and getchar are macros.

Fgetc behaves like getc, but is a function rather than a macro. Fgetc runs more slowly than getc, but it takes less space per invocation and its name can be passed as an argument to a function.

Getw returns the next word (i.e., integer) from the named input stream. Getw increments the associated file pointer, if defined, to point to the next word. The size of a word is the size of an integer and varies from machine to machine. Getw assumes no special alignment in the file.

#### SEE ALSO

fclose(3S), ferror(3S), fopen(3S), fread(3S), gets(3S), putc(3S), scanf(3S).

#### DIAGNOSTICS

These functions return the constant EOF at end-of-file or upon an error. Because EOF is a valid integer, ferror (3S) should be used to detect getw errors.

#### WARNING

If the integer value returned by getc, getchar, or fgetc is stored into a character variable and then compared against the integer constant EOF, the comparison may never succeed, because sign-extension of a character on widening to integer is machine-dependent.

# BUGS

Because it is implemented as a macro, getc treats incorrectly a stream argument with side effects. In particular, getc(\*f++) does not work sensibly. Fgetc should be used instead.

Because of possible differences in word length and byte ordering, files written using *putw* are machine-dependent, and may not be read using *getw* on a different processor.

getcwd - get path-name of current working directory

## SYNOPSIS

```
char *getcwd (buf, size)
char *buf;
int size;
```

## DESCRIPTION

Getcwd returns a pointer to the current directory path name. The value of size must be at least two greater than the length of the path-name to be returned.

If buf is a NULL pointer, getcwd will obtain size bytes of space using malloc(3C). In this case, the pointer returned by getcwd may be used as the argument in a subsequent call to free.

The function is implemented by using popen(3S) to pipe the output of the pwd(1) command into the specified string space.

### **EXAMPLE**

# SEE ALSO

malloc(3C), popen(3S). pwd(1) in the 3B2 Computer System User Reference Manual.

# DIAGNOSTICS

Returns NULL with errno set if size is not large enough, or if an error ocurrs in a lower-level function.

getenv - return value for environment name

# SYNOPSIS

char \*getenv (name) char \*name;

# DESCRIPTION

Getenv searches the environment list (see environ(5)) for a string of the form name = value, and returns a pointer to the value in the current environment if such a string is present, otherwise a NULL pointer.

#### SEE ALSO

exec(2), putenv(3C), environ(5).

getgrent, getgrgid, getgrnam, setgrent, endgrent, fgetgrent — get group file entry

## **SYNOPSIS**

```
#include <grp.h>
struct group *getgrent ( )
struct group *getgrgid (gid)
int gid;
struct group *getgrnam (name)
char *name;
void setgrent ( )
void endgrent ( )
struct group *fgetgrent (f)
FILE *f;
```

#### DESCRIPTION

Getgrent, getgrgid and getgrnam each return pointers to an object with the following structure containing the broken-out fields of a line in the /etc/group file. Each line contains a "group" structure, defined in the /grp.h> header file.

```
struct group {
    char *gr_name; /* the name of the group */
    char *gr_passwd; /* the encrypted group password */
    int gr_gid; /* the numerical group ID */
    char **gr_mem; /* vector of pointers to member names */
};
```

Getgrent when first called returns a pointer to the first group structure in the file; thereafter, it returns a pointer to the next group structure in the file; so, successive calls may be used to search the entire file. Getgrgid searches from the beginning of the file until a numerical group id matching gid is found and returns a pointer to the particular structure in which it was found. Getgrnam searches from the beginning of the file until a group name matching name is found and returns a pointer to the particular structure in which it was found. If an end-of-file or an error is encountered on reading, these functions return a NULL pointer.

A call to *setgrent* has the effect of rewinding the group file to allow repeated searches. *Endgrent* may be called to close the group file when processing is complete.

Fgetgrent returns a pointer to the next group structure in the stream f, which matches the format of /etc/group.

# **FILES**

/etc/group

## SEE ALSO

getlogin(3C), getpwent(3C), group(4).

# DIAGNOSTICS

A NULL pointer is returned on EOF or error.

#### WARNING

The above routines use **<stdio.h>**, which causes them to increase the size of programs, not otherwise using standard I/O, more than might be expected.

## **BUGS**

All information is contained in a static area, so it must be copied if it is to be saved.

getlogin - get login name

**SYNOPSIS** 

char \*getlogin ();

# DESCRIPTION

Getlogin returns a pointer to the login name as found in /etc/utmp. It may be used in conjunction with getpwnam to locate the correct password file entry when the same user ID is shared by several login names.

If getlogin is called within a process that is not attached to a terminal, it returns a NULL pointer. The correct procedure for determining the login name is to call cuserid, or to call getlogin and if it fails to call getpwuid.

**FILES** 

/etc/utmp

SEE ALSO

cuserid(3S), getgrent(3C), getpwent(3C), utmp(4).

DIAGNOSTICS

Returns the NULL pointer if name is not found.

**BUGS** 

The return values point to static data whose content is overwritten by each call.

getopt - get option letter from argument vector

## **SYNOPSIS**

```
int getopt (argc, argv, optstring)
int argc;
char **argv, *opstring;
extern char *optarg;
extern int optind, opterr;
```

#### DESCRIPTION

Getopt returns the next option letter in argv that matches a letter in optstring. Optstring is a string of recognized option letters; if a letter is followed by a colon, the option is expected to have an argument that may or may not be separated from it by white space. Optarg is set to point to the start of the option argument on return from getopt.

Getopt places in optind the argv index of the next argument to be processed. Because optind is external, it is normally initialized to zero automatically before the first call to getopt.

When all options have been processed (i.e., up to the first non-option argument), getopt returns EOF. The special option - may be used to delimit the end of the options; EOF will be returned, and - will be skipped.

## DIAGNOSTICS

Getopt prints an error message on stderr and returns a question mark (?) when it encounters an option letter not included in optstring. This error message may be disabled by setting opterr to a non-zero value.

#### **EXAMPLE**

The following code fragment shows how one might process the arguments for a command that can take the mutually exclusive options a and b, and the options f and o, both of which require arguments:

```
main (argc, argv)
int argc;
char **argv;
        int c:
        extern char *optarg;
        extern int optind;
        while ((c = getopt(argc, argv, "abf:o:")) != EOF)
                 switch (c) {
                 case 'a':
                         if (bflg)
                                 errflg++;
                         else
                                  aflg++;
                         break;
                 case 'b':
                         if (aflg)
                                  errflg++;
                         else
                                  bproc();
                         break:
                 case 'f':
                         ifile = optarg;
                         break;
```

getpass - read a password

SYNOPSIS

char \*getpass (prompt)
char \*prompt;

# **DESCRIPTION**

Getpass reads up to a newline or EOF from the file /dev/tty, after prompting on the standard error output with the null-terminated string prompt and disabling echoing. A pointer is returned to a null-terminated string of at most 8 characters. If /dev/tty cannot be opened, a NULL pointer is returned. An interrupt will terminate input and send an interrupt signal to the calling program before returning.

#### **FILES**

/dev/tty

# WARNING

The above routine uses <stdio.h>, which causes it to increase the size of programs not otherwise using standard I/O, more than might be expected.

## **BUGS**

10/84

The return value points to static data whose content is overwritten by each call.

getpw - get name from UID

## SYNOPSIS

int getpw (uid, buf) int uid; char \*buf;

# DESCRIPTION

Getpw searches the password file for a user id number that equals uid, copies the line of the password file in which uid was found into the array pointed to by buf, and returns 0. Getpw returns non-zero if uid cannot be found.

This routine is included only for compatibility with prior systems and should not be used; see *getpwent* (3C) for routines to use instead.

# **FILES**

/etc/passwd

# **SEE ALSO**

getpwent (3C), passwd (4).

# DIAGNOSTICS

Getpw returns non-zero on error.

## WARNING

The above routine uses **<stdio.h>**, which causes it to increase, more than might be expected, the size of programs not otherwise using standard I/O.

getpwent, getpwuid, getpwnam, setpwent, endpwent, fgetpwent - get password file entry

## **SYNOPSIS**

```
#include <pwd.h>
struct passwd *getpwent ( )
struct passwd *getpwuid (uid)
int uid;
struct passwd *getpwnam (name)
char *name;
void setpwent ( )
void endpwent ( )
struct passwd *fgetpwent (f)
FILE *f;
```

#### DESCRIPTION

Getpwent, getpwuid and getpwnam each returns a pointer to an object with the following structure containing the broken-out fields of a line in the /etc/passwd file. Each line in the file contains a "passwd" structure, declared in the <pwd.h> header file:

```
struct passwd {
        char
                *pw name:
        char
                *pw passwd;
        int
                pw uid;
        int
                pw gid;
        char
                *pw_age;
        char
                *pw_comment;
        char
                *pw gecos;
                *pw_dir;
        char
        char
                *pw shell;
};
```

This structure is declared in < pwd.h > so it is not necessary to redeclare it.

The  $pw\_comment$  field is unused; the others have meanings described in  $passwd(\overline{4})$ .

Getpwent when first called returns a pointer to the first passwd structure in the file; thereafter, it returns a pointer to the next passwd structure in the file; so successive calls can be used to search the entire file. Getpwuid searches from the beginning of the file until a numerical user id matching uid is found and returns a pointer to the particular structure in which it was found. Getpwnam searches from the beginning of the file until a login name matching name is found, and returns a pointer to the particular structure in which it was found. If an end-of-file or an error is encountered on reading, these functions return a NULL pointer.

A call to *setpwent* has the effect of rewinding the password file to allow repeated searches. *Endpwent* may be called to close the password file when processing is complete.

Fgetpwent returns a pointer to the next passwd structure in the stream f, which matches the format of /etc/passwd.

# **FILES**

/etc/passwd

# SEE ALSO

getlogin(3C), getgrent(3C), passwd(4).

# DIAGNOSTICS

A NULL pointer is returned on EOF or error.

# WARNING

The above routines use **<stdio.h>**, which causes them to increase the size of programs, not otherwise using standard I/O, more than might be expected.

# **BUGS**

All information is contained in a static area, so it must be copied if it is to be saved.

gets, fgets - get a string from a stream

## **SYNOPSIS**

#include <stdio.h>

char \*gets (s)

char \*s;

char \*fgets (s, n, stream)

char \*s;

int n;

FILE \*stream;

#### DESCRIPTION

Gets reads characters from the standard input stream, stdin, into the array pointed to by s, until a new-line character is read or an end-of-file condition is encountered: The new-line character is discarded and the string is terminated with a null character.

Fgets reads characters from the stream into the array pointed to by s, until n-1 characters are read, or a new-line character is read and transferred to s, or an end-of-file condition is encountered. The string is then terminated with a null character.

## SEE ALSO

ferror(3S), fopen(3S), fread(3S), getc(3S), scanf(3S).

#### DIAGNOSTICS

If end-of-file is encountered and no characters have been read, no characters are transferred to s and a NULL pointer is returned. If a read error occurs, such as trying to use these functions on a file that has not been opened for reading, a NULL pointer is returned. Otherwise s is returned.

getutent, getutid, getutline, pututline, setutent, endutent, utmpname — access utmp file entry

#### **SYNOPSIS**

```
#include <utmp.h>
struct utmp *getutent ()
struct utmp *getutid (id)
struct utmp *id;
struct utmp *getutline (line)
struct utmp *line;
void pututline (utmp)
struct utmp *utmp;
void setutent ()
void endutent ()
void utmpname (file)
char *file;
```

## DESCRIPTION

Getutent, getutid and getutline each return a pointer to a structure of the following type:

```
struct utmp {
       char
                 ut user[8]:
                                    /* User login name */
       char
                 ut id[4];
                                    /* /etc/inittab id (usually line #) */
       char
                 ut line[12];
                                    /* device name (console, lnxx) */
       short
                 ut pid;
                                    /* process id */
       short
                                    /* type of entry */
                 ut type;
       struct
                 exit status {
                    e termination; /* Process termination status */
          short
                                    /* Process exit status */
          short
                    e exit;
                                    /* The exit status of a process
       dut exit;
                                     * marked as DEAD PROCESS. */
       time t
                 ut time:
                                    /* time entry was made */
}:
```

Getutent reads in the next entry from a utmp-like file. If the file is not already open, it opens it. If it reaches the end of the file, it fails.

Getutid searches forward from the current point in the utmp file until it finds an entry with a  $ut\_type$  matching  $id->ut\_type$  if the type specified is RUN\_LVL, BOOT\_TIME, OLD\_TIME or NEW\_TIME. If the type specified in id is INIT\_PROCESS, LOGIN\_PROCESS, USER\_PROCESS or DEAD\_PROCESS, then getutid will return a pointer to the first entry whose type is one of these four and whose  $ut\_id$  field matches  $id->ut\_id$ . If the end of file is reached without a match, it fails.

Getutline searches forward from the current point in the utmp file until it finds an entry of the type LOGIN\_PROCESS or USER\_PROCESS which also has a  $ut\_line$  string matching the  $line -> ut\_line$  string. If the end of file is reached without a match, it fails.

Pututline writes out the supplied utmp structure into the utmp file. It uses getutid to search forward for the proper place if it finds that it is not already at the proper place. It is expected that normally the user of pututline will have searched for the proper entry using one of the getut routines. If so, pututline will not search. If pututline does not find a matching slot for the new entry, it will add a new entry to the end of the file.

Setutent resets the input stream to the beginning of the file. This should be done before each search for a new entry if it is desired that the entire file be examined.

Endutent closes the currently open file.

Utmpname allows the user to change the name of the file examined, from /etc/utmp to any other file. It is most often expected that this other file will be /etc/wtmp. If the file does not exist, this will not be apparent until the first attempt to reference the file is made. Utmpname does not open the file. It just closes the old file if it is currently open and saves the new file name.

#### **FILES**

/etc/utmp /etc/wtmp

## SEE ALSO

ttyslot(3C), utmp(4).

## DIAGNOSTICS

A NULL pointer is returned upon failure to read, whether for permissions or having reached the end of file, or upon failure to write.

#### COMMENTS

The most current entry is saved in a static structure. Multiple accesses require that it be copied before further accesses are made. Each call to either *getutid* or *getutline* sees the routine examine the static structure before performing more I/O. If the contents of the static structure match what it is searching for, it looks no further. For this reason to use *getutline* to search for multiple occurrences, it would be necessary to zero out the static after each success, or *getutline* would just return the same pointer over and over again. There is one exception to the rule about removing the structure before further reads are done. The implicit read done by *pututline* (if it finds that it is not already at the correct place in the file) will not hurt the contents of the static structure returned by the *getutent*, *getutid* or *getutline* routines, if the user has just modified those contents and passed the pointer back to *pututline*.

These routines use buffered standard I/O for input, but *pututline* uses an unbuffered non-standard write to avoid race conditions between processes trying to modify the *utmp* and *wtmp* files.

hsearch, hcreate, hdestroy - manage hash search tables

#### SYNOPSIS

#include <search.h>

ENTRY \*hsearch (item, action)

ENTRY item;

**ACTION action**;

int hcreate (nel)

unsigned nel; void hdestroy ( )

#### DESCRIPTION

Hsearch is a hash-table search routine generalized from Knuth (6.4) Algorithm D. It returns a pointer into a hash table indicating the location at which an entry can be found. Item is a structure of type ENTRY (defined in the <search.h> header file) containing two pointers: item.key points to the comparison key, and item.data points to any other data to be associated with that key. (Pointers to types other than character should be cast to pointer-to-character.) Action is a member of an enumeration type ACTION indicating the disposition of the entry if it cannot be found in the table. ENTER indicates that the item should be inserted in the table at an appropriate point. FIND indicates that no entry should be made. Unsuccessful resolution is indicated by the return of a NULL pointer.

Hcreate allocates sufficient space for the table, and must be called before hsearch is used. Nel is an estimate of the maximum number of entries that the table will contain. This number may be adjusted upward by the algorithm in order to obtain certain mathematically favorable circumstances.

Hdestroy destroys the search table, and may be followed by another call to hcreate.

# **NOTES**

Hsearch uses open addressing with a multiplicative hash function. However, its source code has many other options available which the user may select by compiling the hsearch source with the following symbols defined to the preprocessor:

DIV Use the *remainder modulo table size* as the hash function instead of the multiplicative algorithm.

USCR Use a User Supplied Comparison Routine for ascertaining table membership. The routine should be named *hcompar* and should behave in a mannner similar to *strcmp* (see *string*(3C)).

CHAINED Use a linked list to resolve collisions. If this option is selected, the following other options become available.

START Place new entries at the beginning of the

linked list (default is at the end).

SORTUP Keep the linked list sorted by key in ascending order.

SORTDOWN Keep the linked list sorted by key in descending order.

Additionally, there are preprocessor flags for obtaining debugging printout (-DDEBUG) and for including a test driver in the calling routine (-DDRIVER). The source code should be consulted for further details.

#### **EXAMPLE**

The following example will read in strings followed by two numbers and store them in a hash table, discarding duplicates. It will then read in strings and find the matching entry in the hash table and print it out.

```
#include <stdio.h>
#include <search.h>
                       /* this is the info stored in the table */
struct info {
       int age, room; /* other than the key. */
                       5000
                                /* # of elements in search table */
#define NUM EMPL
main()
       /* space to store strings */
       char string space[NUM EMPL*20];
       /* space to store employee info */
       struct info info space[NUM_EMPL];
       /* next avail space in string space */
       char *str_ptr = string_space;
       /* next avail space in info space */
       struct info *info ptr = info space;
       ENTRY item, *found_item, *hsearch();
       /* name to look for in table */
       char name to find[30];
       int i = 0;
       /* create table */
        (void) hcreate(NUM_EMPL);
       while (scanf("%s%d%d", str_ptr, &info_ptr->age,
               &info ptr->room) != EOF && i++ < NUM EMPL) {
               /* put info in structure, and structure in item */
               item.key = str_ptr;
               item.data = (char *)info ptr;
               str_ptr += strlen(str_ptr) + 1;
               info_ptr++;
               /* put item into table */
               (void) hsearch(item, ENTER);
       }
       /* access table */
       item.key = name_to_find;
       while (scanf("%s", item.key) != EOF) {
            if ((found_item = hsearch(item, FIND)) != NULL) {
               /* if item is in the table */
               (void) printf ("found %s, age = %d, room = %d\n",
                       found_item->key,
                       ((struct info *)found_item->data)->age,
                       ((struct info *)found item->data)->room);
            } else {
               (void) printf ("no such employee %s\n",
                       name to find)
       }
```

}

# SEE ALSO

bsearch(3C), lsearch(3C), malloc(3C), malloc(3X), string(3C), tsearch(3C).

# DIAGNOSTICS

Hsearch returns a NULL pointer if either the action is FIND and the item could not be found or the action is ENTER and the table is full.

Hcreate returns zero if it cannot allocate sufficient space for the table.

# WARNING

Hsearch and hcreate use malloc (3C) to allocate space.

# **BUGS**

Only one hash search table may be active at any given time.

13tol, Itol3 – convert between 3-byte integers and long integers

# **SYNOPSIS**

```
void 13tol (lp, cp, n)
long *lp;
char *cp;
int n;
void Itol3 (cp, lp, n)
char *cp;
long *lp;
int n;
```

# DESCRIPTION

L3tol converts a list of n three-byte integers packed into a character string pointed to by cp into a list of long integers pointed to by lp.

Ltol3 performs the reverse conversion from long integers (lp) to three-byte integers (cp).

These functions are useful for file-system maintenance where the block numbers are three bytes long.

# SEE ALSO

fs(4).

## **BUGS**

Because of possible differences in byte ordering, the numerical values of the long integers are machine-dependent.

lockf - record locking on files

**SYNOPSIS** 

# include <unistd.h>

lockf (fildes, function, size) long size; int fildes, function;

# DESCRIPTION

The lockf command will allow sections of a file to be locked (advisory write locks). (Mandatory or enforcement mode record locks are not currently available.) Locking calls from other processes which attempt to lock the locked file section will either return an error value or be put to sleep until the resource becomes unlocked. All the locks for a process are removed when the process terminates. (See fcntl(2) for more information about record locking.)

Fildes is an open file descriptor. The file descriptor must have O\_WRONLY or O RDWR permission in order to establish lock with this function call.

Function is a control value which specifies the action to be taken. The permissible values for function are defined in <unistd.h> as follows:

```
/* Unlock a previously locked section */
                        0
#define
          F ULOCK
#define
          F LOCK
                        1
                             /* Lock a section for exclusive use */
            TLOCK
                        2
                             /* Test and lock a section for exclusive use */
#define
#define
          F TEST
                        3
                             /* Test section for other processes locks */
```

All other values of *function* are reserved for future extensions and will result in an error return if not implemented.

F\_TEST is used to detect if a lock by another process is present on the specified section. F\_LOCK and F\_TLOCK both lock a section of a file if the section is available. F UNLOCK removes locks from a section of the file.

Size is the number of contiguous bytes to be locked or unlocked. The resource to be locked starts at the current offset in the file and extends forward for a positive size and backward for a negative size (the preceding bytes up to but not including the current offset). If size is zero, the section from the current offset through the largest file offset is locked (i.e., from the current offset through the present or any future end-of-file). An area need not be allocated to the file in order to be locked as such locks may exist past the end-of-file.

The sections locked with F\_LOCK or F\_TLOCK may, in whole or in part, contain or be contained by a previously locked section for the same process. When this occurs, or if adjacent sections occur, the sections are combined into a single section. If the request requires that a new element be added to the table of active locks and this table is already full, an error is returned, and the new section is not locked.

F\_LOCK and F\_TLOCK requests differ only by the action taken if the resource is not available. F\_LOCK will cause the calling process to sleep until the resource is available. F\_TLOCK will cause the function to return a -1 and set errno to [EACCESS] error if the section is already locked by another process.

F\_ULOCK requests may, in whole or in part, release one or more locked sections controlled by the process. When sections are not fully released, the remaining sections are still locked by the process. Releasing the center section of a locked section requires an additional element in the table of active locks. If this table is full, an [EDEADLK] error is returned and the requested section is not

#### released.

A potential for deadlock occurs if a process controlling a locked resource is put to sleep by accessing another process's locked resource. Thus calls to *lock* or *fcntl* scan for a deadlock prior to sleeping on a locked resource. An error return is made if sleeping on the locked resource would cause a deadlock.

Sleeping on a resource is interrupted with any signal. The *alarm*(2) command may be used to provide a timeout facility in applications which require this facility.

# **ERRORS**

The lockf utility will fail if one or more of the following are true:

## [EBADF]

Fildes is not a valid open descriptor.

## [EACCESS]

 $\mathit{Cmd}$  is F\_TLOCK or F\_TEST and the section is already locked by another process.

### [EDEADLK]

Cmd is F\_LOCK or F\_TLOCK and a deadlock would occur. Also the cmd is either of the above or F\_ULOCK and the number of entries in the lock table would exceed the number allocated on the system.

## SEE ALSO

close(2), creat(2), fcntl(2), intro(2), open(2), read(2), write(2).

## RETURN VALUE

Upon successful completion, a value of 0 is returned. Otherwise, a value of -1 is returned and *errno* is set to indicate the error.

## WARNINGS

Unexpected results may occur in processes that do buffering in the user address space. The process may later read/write data which is/was locked. The standard I/O package is the most common source of unexpected buffering.

lsearch, lfind - linear search and update

#### SYNOPSIS

```
#include <stdio.h>
#include <search.h>
char *lsearch ((char *)key, (char *)base, nelp, sizeof(*key), compar)
unsigned *nelp;
int (*compar)();
char *lfind ((char *)key, (char *)base, nelp, sizeof(*key), compar)
unsigned *nelp;
int (*compar)();
```

#### DESCRIPTION

Lsearch is a linear search routine generalized from Knuth (6.1) Algorithm S. It returns a pointer into a table indicating where a datum may be found. If the datum does not occur, it is added at the end of the table. Key points to the datum to be sought in the table. Base points to the first element in the table. Nelp points to an integer containing the current number of elements in the table. The integer is incremented if the datum is added to the table. Compar is the name of the comparison function which the user must supply (strcmp, for example). It is called with two arguments that point to the elements being compared. The function must return zero if the elements are equal and non-zero otherwise.

Lfind is the same as *lsearch* except that if the datum is not found, it is not added to the table. Instead, a NULL pointer is returned.

## **NOTES**

The pointers to the key and the element at the base of the table should be of type pointer-to-element, and cast to type pointer-to-character.

The comparison function need not compare every byte, so arbitrary data may be contained in the elements in addition to the values being compared.

Although declared as type pointer-to-character, the value returned should be cast into type pointer-to-element.

## **EXAMPLE**

This fragment will read in  $\leq$  TABSIZE strings of length  $\leq$  ELSIZE and store them in a table, eliminating duplicates.

#### SEE ALSO

bsearch(3C), hsearch(3C), tsearch(3C).

# DIAGNOSTICS

If the searched for datum is found, both *lsearch* and *lfind* return a pointer to it. Otherwise, *lfind* returns NULL and *lsearch* returns a pointer to the newly added element.

# **BUGS**

Undefined results can occur if there is not enough room in the table to add a new item.

malloc, free, realloc, calloc - main memory allocator

## **SYNOPSIS**

char \*malloc (size)
unsigned size;
void free (ptr)
char \*ptr;
char \*realloc (ptr, size)
char \*ptr;
unsigned size;
char \*calloc (nelem, elsize)
unsigned nelem, elsize;

## DESCRIPTION

Malloc and free provide a simple general-purpose memory allocation package. Malloc returns a pointer to a block of at least size bytes suitably aligned for any use.

The argument to *free* is a pointer to a block previously allocated by *malloc*; after *free* is performed this space is made available for further allocation, but its contents are left undisturbed.

Undefined results will occur if the space assigned by *malloc* is overrun or if some random number is handed to *free*.

Malloc allocates the first big enough contiguous reach of free space found in a circular search from the last block allocated or freed, coalescing adjacent free blocks as it searches. It calls sbrk (see brk(2)) to get more memory from the system when there is no suitable space already free.

Realloc changes the size of the block pointed to by ptr to size bytes and returns a pointer to the (possibly moved) block. The contents will be unchanged up to the lesser of the new and old sizes. If no free block of size bytes is available in the storage arena, then realloc will ask malloc to enlarge the arena by size bytes and will then move the data to the new space.

Realloc also works if ptr points to a block freed since the last call of malloc, realloc, or calloc; thus sequences of free, malloc and realloc can exploit the search strategy of malloc to do storage compaction.

Calloc allocates space for an array of nelem elements of size elsize. The space is initialized to zeros.

Each of the allocation routines returns a pointer to space suitably aligned (after possible pointer coercion) for storage of any type of object.

# SEE ALSO

brk(2), malloc(3X).

#### DIAGNOSTICS

Malloc, realloc and calloc return a NULL pointer if there is no available memory or if the arena has been detectably corrupted by storing outside the bounds of a block. When this happens the block pointed to by ptr may be destroyed.

## **NOTES**

Search time increases when many objects have been allocated; that is, if a program allocates but never frees, then each successive allocation takes longer. For an alternate, more flexible implementation, see *malloc*(3X).

memccpy, memchr, memcmp, memcpy, memset - memory operations

## SYNOPSIS

```
#include <memory.h>
char *memccpy (s1, s2, c, n)
char *s1, *s2;
int c, n;
char *memchr (s, c, n)
char *s;
int c, n;
int memcmp (s1, s2, n)
char *s1, *s2;
int n:
char *memcpy (s1, s2, n)
char *s1, *s2;
int n;
char *memset (s, c, n)
char *s;
int c, n;
```

# DESCRIPTION

These functions operate as efficiently as possible on memory areas (arrays of characters bounded by a count, not terminated by a null character). They do not check for the overflow of any receiving memory area.

Memccpy copies characters from memory area s2 into s1, stopping after the first occurrence of character c has been copied, or after n characters have been copied, whichever comes first. It returns a pointer to the character after the copy of c in s1, or a NULL pointer if c was not found in the first n characters of s2.

Memchr returns a pointer to the first occurrence of character c in the first n characters of memory area s, or a NULL pointer if c does not occur.

Memcmp compares its arguments, looking at the first n characters only, and returns an integer less than, equal to, or greater than 0, according as s1 is lexicographically less than, equal to, or greater than s2.

Memcpy copies n characters from memory area s2 to s1. It returns s1.

Memset sets the first n characters in memory area s to the value of character c. It returns s.

For user convenience, all these functions are declared in the optional <memory.h> header file.

# **BUGS**

Memcmp uses native character comparison, which is unsigned. Thus the sign of the value returned when one of the characters has its high-order bit set is implementation-dependent.

Character movement is performed differently in different implementations. Thus overlapping moves may yield surprises.

mktemp - make a unique file name

# **SYNOPSIS**

char \*mktemp (template)
char \*template;

# DESCRIPTION

Mktemp replaces the contents of the string pointed to by template by a unique file name, and returns the address of template. The string in template should look like a file name with six trailing Xs; mktemp will replace the Xs with a letter and the current process ID. The letter will be chosen so that the resulting name does not duplicate an existing file.

# SEE ALSO

getpid(2), tmpfile(3S), tmpnam(3S).

# **BUGS**

It is possible to run out of letters.

monitor - prepare execution profile

## **SYNOPSIS**

#include <mon.h>

void monitor (lowpc, highpc, buffer, bufsize, nfunc)
int (\*lowpc)( ), (\*highpc)( );
WORD \*buffer;
int bufsize, nfunc;

#### DESCRIPTION

An executable program created by cc - p automatically includes calls for *monitor* with default parameters; *monitor* needn't be called explicitly except to gain fine control over profiling.

Monitor is an interface to profil(2). Lowpc and highpc are the addresses of two functions; buffer is the address of a (user supplied) array of bufsize WORDs (defined in the < mon.h> header file). Monitor arranges to record a histogram of periodically sampled values of the program counter, and of counts of calls of certain functions, in the buffer. The lowest address sampled is that of lowpc and the highest is just below highpc. Lowpc may not equal 0 for this use of monitor. At most nfunc call counts can be kept; only calls of functions compiled with the profiling option  $-\mathbf{p}$  of cc(1) are recorded.

For the results to be significant, especially where there are small, heavily used routines, it is suggested that the buffer be no more than a few times smaller than the range of locations sampled.

To profile the entire program, it is sufficient to use

extern etext;

monitor ((int (\*)())2, etext, buf, bufsize, nfunc);

Etext lies just above all the program text; see end (3C).

To stop execution monitoring and write the results on the file **mon.out**, use monitor ((int (\*)())0, 0, 0, 0, 0);

Prof(1) can then be used to examine the results.

# FILES

mon.out /lib/libp/libc.a /lib/libp/libm.a

nlist - get entries from name list

#### SYNOPSIS

#include <nlist.h>
int nlist (file-name, nl)
char \*file-name;
struct nlist \*nl;

## DESCRIPTION

Nlist examines the name list in the executable file whose name is pointed to by file-name, and selectively extracts a list of values and puts them in the array of nlist structures pointed to by nl. The name list nl consists of an array of structures containing names of variables, types and values. The list is terminated with a null name; that is, a null string is in the name position of the structure. Each variable name is looked up in the name list of the file. If the name is found, the type and value of the name are inserted in the next two fields. The type field will be set to 0 unless the file was compiled with the -g option. If the name is not found, both entries are set to 0. See a.out(4) for a discussion of the symbol table structure.

This function is useful for examining the system name list kept in the file /unix. In this way programs can obtain system addresses that are up to date.

# NOTES

The  $\langle nlist.h \rangle$  header file is automatically included by  $\langle a.out.h \rangle$  for compatability. However, if the only information needed from  $\langle a.out.h \rangle$  is for use of nlist, then including  $\langle a.out.h \rangle$  is discouraged. If  $\langle a.out.h \rangle$  is included, the line "#undef n name" may need to follow it.

# SEE ALSO

a.out(4).

## DIAGNOSTICS

All value entries are set to 0 if the file cannot be read or if it does not contain a valid name list.

Nlist returns -1 upon error; otherwise it returns 0.

perror, errno, sys errlist, sys nerr - system error messages

# **SYNOPSIS**

void perror (s)
char \*s;
extern int errno;
extern char \*sys\_errlist[ ];
extern int sys nerr;

# DESCRIPTION

Perror produces a message on the standard error output, describing the last error encountered during a call to a system or library function. The argument string s is printed first, then a colon and a blank, then the message and a new-line. To be of most use, the argument string should include the name of the program that incurred the error. The error number is taken from the external variable errno, which is set when errors occur but not cleared when non-erroneous calls are made.

To simplify variant formatting of messages, the array of message strings  $sys\_errlist$  is provided; errno can be used as an index in this table to get the message string without the new-line.  $Sys\_nerr$  is the largest message number provided for in the table; it should be checked because new error codes may be added to the system before they are added to the table.

## SEE ALSO

intro(2).

popen, pclose - initiate pipe to/from a process

## **SYNOPSIS**

#include <stdio.h>

FILE \*popen (command, type) char \*command, \*type;

int pclose (stream)
FILE \*stream:

## DESCRIPTION

The arguments to popen are pointers to null-terminated strings containing, respectively, a shell command line and an I/O mode, either r for reading or w for writing. Popen creates a pipe between the calling program and the command to be executed. The value returned is a stream pointer such that one can write to the standard input of the command, if the I/O mode is w, by writing to the file stream; and one can read from the standard output of the command, if the I/O mode is r, by reading from the file stream.

A stream opened by *popen* should be closed by *pclose*, which waits for the associated process to terminate and returns the exit status of the command.

Because open files are shared, a type r command may be used as an input filter and a type w as an output filter.

#### SEE ALSO

pipe(2), wait(2), fclose(3S), fopen(3S), system(3S).

#### DIAGNOSTICS

Popen returns a NULL pointer if files or processes cannot be created, or if the shell cannot be accessed.

Pclose returns -1 if stream is not associated with a "popened" command.

## **BUGS**

If the original and "popened" processes concurrently read or write a common file, neither should use buffered I/O, because the buffering gets all mixed up. Problems with an output filter may be forestalled by careful buffer flushing, e.g. with fflush; see fclose (3S).

```
NAME
```

printf, fprintf, sprintf - print formatted output

#### **SYNOPSIS**

```
#include <stdio.h>
int printf (format [ , arg ] ... )
char *format;
int fprintf (stream, format [ , arg ] ... )
FILE *stream;
char *format;
int sprintf (s, format [ , arg ] ... )
char *s, format;
```

# DESCRIPTION

Printf places output on the standard output stream stdout. Fprintf places output on the named output stream. Sprintf places "output," followed by the null character (\0), in consecutive bytes starting at \*s; it is the user's responsibility to ensure that enough storage is available. Each function returns the number of characters transmitted (not including the \0 in the case of sprintf), or a negative value if an output error was encountered.

Each of these functions converts, formats, and prints its args under control of the format. The format is a character string that contains two types of objects: plain characters, which are simply copied to the output stream, and conversion specifications, each of which results in fetching of zero or more args. The results are undefined if there are insufficient args for the format. If the format is exhausted while args remain, the excess args are simply ignored.

Each conversion specification is introduced by the character %. After the %, the following appear in sequence:

Zero or more flags, which modify the meaning of the conversion specification.

An optional decimal digit string specifying a minimum field width. If the converted value has fewer characters than the field width, it will be padded on the left (or right, if the left-adjustment flag '—', described below, has been given) to the field width. If the field width for an s conversion is preceded by a 0, the string is right adjusted with zero-padding on the left.

A precision that gives the minimum number of digits to appear for the d, o, u, x, or X conversions, the number of digits to appear after the decimal point for the e and f conversions, the maximum number of significant digits for the g conversion, or the maximum number of characters to be printed from a string in s conversion. The precision takes the form of a period (.) followed by a decimal digit string; a null digit string is treated as zero.

An optional I (ell) specifying that a following d, o, u, x, or X conversion character applies to a long integer arg. A I before any other conversion character is ignored.

A character that indicates the type of conversion to be applied.

A field width or precision may be indicated by an asterisk (\*) instead of a digit string. In this case, an integer arg supplies the field width or precision. The arg that is actually converted is not fetched until the conversion letter is seen, so the args specifying field width or precision must appear before the arg (if any) to be converted.

#

The flag characters and their meanings are:

The result of the conversion will be left-justified within the field.

+ The result of a signed conversion will always begin with a sign (+ or -).

blank

If the first character of a signed conversion is not a sign, a blank
will be prefixed to the result. This implies that if the blank and +
flags both appear, the blank flag will be ignored.

This flag specifies that the value is to be converted to an "alternate form." For c, d, s, and u conversions, the flag has no effect. For o conversion, it increases the precision to force the first digit of the result to be a zero. For x or X conversion, a non-zero result will have 0x or 0X prefixed to it. For e, E, f, g, and G conversions, the result will always contain a decimal point, even if no digits follow the point (normally, a decimal point appears in the result of these conversions only if a digit follows it). For g and G conversions, trailing zeroes will not be removed from the result (which they normally are).

The conversion characters and their meanings are:

d,o,u,x,x

The integer arg is converted to signed decimal, unsigned octal, decimal, or hexadecimal notation (x and X), respectively; the letters abcdef are used for x conversion and the letters ABCDEF for X conversion. The precision specifies the minimum number of digits to appear; if the value being converted can be represented in fewer digits, it will be expanded with leading zeroes. (For compatibility with older versions, padding with leading zeroes may alternatively be specified by prepending a zero to the field width. This does not imply an octal value for the field width.) The default precision is 1. The result of converting a zero value with a precision of zero is a null string.

f The float or double arg is converted to decimal notation in the style "[-]ddd.ddd," where the number of digits after the decimal point is equal to the precision specification. If the precision is missing, six digits are output; if the precision is explicitly 0, no decimal point appears.

e,E The float or double arg is converted in the style "[-]d.ddde±dd," where there is one digit before the decimal point and the number of digits after it is equal to the precision; when the precision is missing, six digits are produced; if the precision is zero, no decimal point appears. The E format code will produce a number with E instead of e introducing the exponent. The exponent always contains at least two digits.

g,G The float or double arg is printed in style f or e (or in style E in the case of a G format code), with the precision specifying the number of significant digits. The style used depends on the value converted: style e will be used only if the exponent resulting from the conversion is less than -4 or greater than the precision. Trailing zeroes are removed from the result; a decimal point appears only if it is followed by a digit.

c The character arg is printed.

s The arg is taken to be a string (character pointer) and characters from the string are printed until a null character (\( \)0) is encountered or the number of characters indicated by the precision specification is reached. If the precision is missing, it is taken to be infinite, so all characters up to the first null character are printed. A NULL value for arg will yield undefined results.

% Print a %; no argument is converted.

In no case does a non-existent or small field width cause truncation of a field; if the result of a conversion is wider than the field width, the field is simply expanded to contain the conversion result. Characters generated by *printf* and *fprintf* are printed as if *putc*(3S) had been called.

# **EXAMPLES**

To print a date and time in the form "Sunday, July 3, 10:02," where weekday and month are pointers to null-terminated strings:

printf("%s, %s %d, %d:%.2d", weekday, month, day, hour, min);

To print  $\pi$  to 5 decimal places:

printf("pi = %.5f", 4 \* atan(1.0));

## SEE ALSO

ecvt(3C), putc(3S), scanf(3S), stdio(3S).

putc, putchar, fputc, putw - put character or word on a stream

#### SYNOPSIS

#include <stdio.h>
int putc (c, stream)
int c;
FILE \*stream;
int putchar (c)
int c;
int fputc (c, stream)
int c;
FILE \*stream;
int putw (w, stream)
int w;
FILE \*stream;

#### DESCRIPTION

Putc writes the character c onto the output stream (at the position where the file pointer, if defined, is pointing). Putchar(c) is defined as putc(c, stdout). Putc and putchar are macros.

Fputc behaves like putc, but is a function rather than a macro. Fputc runs more slowly than putc, but it takes less space per invocation and its name can be passed as an argument to a function.

Putw writes the word (i.e. integer) w to the output stream (at the position at which the file pointer, if defined, is pointing). The size of a word is the size of an integer and varies from machine to machine. Putw neither assumes nor causes special alignment in the file.

Output streams, with the exception of the standard error stream *stderr*, are by default buffered if the output refers to a file and line-buffered if the output refers to a terminal. The standard error output stream *stderr* is by default unbuffered, but use of *freopen* (see *fopen*(3S)) will cause it to become buffered or line-buffered. When an output stream is unbuffered, information is queued for writing on the destination file or terminal as soon as written; when it is buffered, many characters are saved up and written as a block. When it is line-buffered, each line of output is queued for writing on the destination terminal as soon as the line is completed (that is, as soon as a new-line character is written or terminal input is requested). *Setbuf*(3S) or *Setbuf*(3S) may be used to change the stream's buffering strategy.

# SEE ALSO

fclose(3S), ferror(3S), fopen(3S), fread(3S), printf(3S), puts(3S), setbuf(3S).

#### DIAGNOSTICS

On success, these functions each return the value they have written. On failure, they return the constant EOF. This will occur if the file *stream* is not open for writing or if the output file cannot be grown. Because EOF is a valid integer, *ferror*(3S) should be used to detect *putw* errors.

## **BUGS**

Because it is implemented as a macro, *putc* treats incorrectly a *stream* argument with side effects. In particular, putc(c, \*f++); doesn't work sensibly. *Fputc* should be used instead.

Because of possible differences in word length and byte ordering, files written using *putw* are machine-dependent, and may not be read using *getw* on a different processor.

putenv - change or add value to environment

# **SYNOPSIS**

int putenv (string) char \*string;

## DESCRIPTION

String points to a string of the form "name = value." Putenv makes the value of the environment variable name equal to value by altering an existing variable or creating a new one. In either case, the string pointed to by string becomes part of the environment, so altering the string will change the environment. The space used by string is no longer used once a new string-defining name is passed to putenv.

# SEE ALSO

exec(2), getenv(3C), malloc(3C), environ(5).

# DIAGNOSTICS

Putenv returns non-zero if it was unable to obtain enough space via malloc for an expanded environment, otherwise zero.

## WARNINGS

Putenv manipulates the environment pointed to by environ, and can be used in conjunction with getenv. However, envp (the third argument to main) is not changed.

This routine uses malloc (3C) to enlarge the environment.

After putenv is called, environmental variables are not in alphabetical order.

A potential error is to call *putenv* with an automatic variable as the argument, then exit the calling function while *string* is still part of the environment.

putpwent - write password file entry

# SYNOPSIS

#include <pwd.h>
int putpwent (p, f)
struct passwd \*p;
FILE \*f;

# DESCRIPTION

Putpwent is the inverse of getpwent(3C). Given a pointer to a passwd structure created by getpwent (or getpwind or getpwnam), putpwent writes a line on the stream f, which matches the format of /etc/passwd.

# SEE ALSO

getpwent(3C).

# DIAGNOSTICS

Putpwent returns non-zero if an error was detected during its operation, otherwise zero.

# WARNING

The above routine uses <stdio.h>, which causes it to increase the size of programs, not otherwise using standard I/O, more than might be expected.

puts, fputs - put a string on a stream

# **SYNOPSIS**

#include <stdio.h>

int puts (s)

char \*s;

int fputs (s, stream)

char \*s;

FILE \*stream;

## DESCRIPTION

Puts writes the null-terminated string pointed to by s, followed by a new-line character, to the standard output stream stdout.

Fputs writes the null-terminated string pointed to by s to the named output stream.

Neither function writes the terminating null character.

# **SEE ALSO**

ferror(3S), fopen(3S), fread(3S), printf(3S), putc(3S).

## DIAGNOSTICS

Both routines return EOF on error. This will happen if the routines try to write on a file that has not been opened for writing.

#### NOTES

Puts appends a new-line character while fputs does not.

qsort - quicker sort

## **SYNOPSIS**

void qsort ((char \*) base, nel, sizeof (\*base), compar)
unsigned nel;
int (\*compar)();

# DESCRIPTION

Qsort is an implementation of the quicker-sort algorithm. It sorts a table of data in place.

Base points to the element at the base of the table. Nel is the number of elements in the table. Compar is the name of the comparison function, which is called with two arguments that point to the elements being compared. As the function must return an integer less than, equal to, or greater than zero, so must the first argument to be considered be less than, equal to, or greater than the second.

## **NOTES**

The pointer to the base of the table should be of type pointer-to-element, and cast to type pointer-to-character.

The comparison function need not compare every byte, so arbitrary data may be contained in the elements in addition to the values being compared. The order in the output of two items which compare as equal is unpredictable.

# SEE ALSO

bsearch(3C), lsearch(3C), string(3C). sort(1) in the 3B2 Computer System User Reference Manual.

rand, srand - simple random-number generator

# **SYNOPSIS**

int rand ()

void srand (seed) unsigned seed;

# DESCRIPTION

Rand uses a multiplicative congruential random-number generator with period  $2^{32}$  that returns successive pseudo-random numbers in the range from 0 to  $2^{15}-1$ .

Srand can be called at any time to reset the random-number generator to a random starting point. The generator is initially seeded with a value of 1.

## **NOTES**

The spectral properties of *rand* leave a great deal to be desired. *Drand48*(3C) provides a much better, though more elaborate, random-number generator.

# SEE ALSO

drand48(3C).

scanf, fscanf, sscanf - convert formatted input

## **SYNOPSIS**

#### DESCRIPTION

Scanf reads from the standard input stream stdin. Fscanf reads from the named input stream. Sscanf reads from the character string s. Each function reads characters, interprets them according to a format, and stores the results in its arguments. Each expects, as arguments, a control string format described below, and a set of pointer arguments indicating where the converted input should be stored.

The control string usually contains conversion specifications, which are used to direct interpretation of input sequences. The control string may contain:

- 1. White-space characters (blanks, tabs, new-lines, or form-feeds) which, except in two cases described below, cause input to be read up to the next non-white-space character.
- 2. An ordinary character (not %), which must match the next character of the input stream.
- Conversion specifications, consisting of the character %, an optional assignment suppressing character \*, an optional numerical maximum field width, an optional 1 (ell) or h indicating the size of the receiving variable, and a conversion code.

A conversion specification directs the conversion of the next input field; the result is placed in the variable pointed to by the corresponding argument, unless assignment suppression was indicated by \*. The suppression of assignment provides a way of describing an input field which is to be skipped. An input field is defined as a string of non-space characters; it extends to the next inappropriate character or until the field width, if specified, is exhausted. For all descriptors except "[" and "c", white space leading an input field is ignored.

The conversion code indicates the interpretation of the input field; the corresponding pointer argument must usually be of a restricted type. For a suppressed field, no pointer argument is given. The following conversion codes are legal:

- % a single % is expected in the input at this point; no assignment is done.
- d a decimal integer is expected; the corresponding argument should be an integer pointer.
- u an unsigned decimal integer is expected; the corresponding argument should be an unsigned integer pointer.
- o an octal integer is expected; the corresponding argument should be an integer pointer.

ſ

x a hexadecimal integer is expected; the corresponding argument should be an integer pointer.

e,f,g a floating point number is expected; the next field is converted accordingly and stored through the corresponding argument, which should be a pointer to a *float*. The input format for floating point numbers is an optionally signed string of digits, possibly containing a decimal point, followed by an optional exponent field consisting of an E or an e, followed by an optional +, -, or space, followed by an integer.

s a character string is expected; the corresponding argument should be a character pointer pointing to an array of characters large enough to accept the string and a terminating \0, which will be added automatically. The input field is terminated by a white-space character.

c a character is expected; the corresponding argument should be a character pointer. The normal skip over white space is suppressed in this case; to read the next non-space character, use % 1s. If a field width is given, the corresponding argument should refer to a character array; the indicated number of characters is read.

indicates string data and the normal skip over leading white space is suppressed. The left bracket is followed by a set of characters, which we will call the scanset, and a right bracket; the input field is the maximal sequence of input characters consisting entirely of characters in the scanset. The circumflex (^), when it appears as the first character in the scanset, serves as a complement operator and redefines the scanset as the set of all characters not contained in the remainder of the scanset string. There are some conventions used in the construction of the scanset. A range of characters may be represented by the construct first-last, thus [0123456789] may be expressed [0-9]. Using this convention, first must be lexically less than or equal to last, or else the dash will stand for itself. The dash will also stand for itself whenever it is the first or the last character in the scanset. To include the right square bracket as an element of the scanset, it must appear as the first character (possibly preceded by a circumflex) of the scanset, and in this case it will not be syntactically interpreted as the closing bracket. The corresponding argument must point to a character array large enough to hold the data field and the terminating \0, which will be added automatically. At least one character must match for this conversion to be considered successful.

The conversion characters  $\mathbf{d}$ ,  $\mathbf{u}$ ,  $\mathbf{o}$ , and  $\mathbf{x}$  may be preceded by  $\mathbf{l}$  or  $\mathbf{h}$  to indicate that a pointer to **long** or to **short** rather than to **int** is in the argument list. Similarly, the conversion characters  $\mathbf{e}$ ,  $\mathbf{f}$ , and  $\mathbf{g}$  may be preceded by  $\mathbf{l}$  to indicate that a pointer to **double** rather than to **float** is in the argument list. The  $\mathbf{l}$  or  $\mathbf{h}$  modifier is ignored for other conversion characters.

Scanf conversion terminates at EOF, at the end of the control string, or when an input character conflicts with the control string. In the latter case, the offending character is left unread in the input stream.

Scanf returns the number of successfully matched and assigned input items; this number can be zero in the event of an early conflict between an input character and the control string. If the input ends before the first conflict or conversion, EOF is returned.

#### **EXAMPLES**

The call:

int i, n; float x; char name[50]; n = scanf ("%d%f%s", &i, &x, name);

with the input line:

25 54.32E-1 thompson

will assign to n the value 3, to i the value 25, to x the value 5.432, and name will contain **thompson\0**. Or:

int i; float x; char name[50]; (void) scanf ("%2d%f%\*d %[0-9]", &i, &x, name);

with input:

56789 0123 56a72

will assign 56 to i, 789.0 to x, skip 0123, and place the string  $56\0$  in name. The next call to getchar (see getc(3S)) will return a.

## SEE ALSO

getc(3S), printf(3S), strtod(3C), strtol(3C).

# DIAGNOSTICS

These functions return EOF on end of input and a short count for missing or illegal data items.

## **BUGS**

The success of literal matches and suppressed assignments is not directly determinable.

Trailing white space (including a new-line) is left unread unless matched in the control string.

setbuf, setvbuf - assign buffering to a stream

## SYNOPSIS

#include <stdio.h>

void setbuf (stream, buf)

FILE \*stream;

char \*buf:

int setvbuf (stream, buf, type, size)

FILE \*stream;

char \*buf;

int type, size;

## DESCRIPTION

Setbuf may be used after a stream has been opened but before it is read or written. It causes the array pointed to by buf to be used instead of an automatically allocated buffer. If buf is the NULL pointer input/output will be completely unbuffered.

A constant BUFSIZ, defined in the <stdio.h> header file, tells how big an array is needed:

char buf[BUFSIZ];

Setvbuf may be used after a stream has been opened but before it is read or written. Type determines how stream will be buffered. Legal values for type (defined in stdio.h) are:

**IOFBF** 

causes input/output to be fully buffered.

\_IOLBF

causes output to be line buffered; the buffer will be flushed when a newline is written, the buffer is full, or input is requested.

**IONBF** 

causes input/output to be completely unbuffered.

If buf is not the NULL pointer, the array it points to will be used for buffering, instead of an automatically allocated buffer. Size specifies the size of the buffer to be used. The constant BUFSIZ in <stdio.h> is suggested as a good buffer size. If input/output is unbuffered, buf and size are ignored.

By default, output to a terminal is line buffered and all other input/output is fully buffered.

#### SEE ALSO

fopen(3S), getc(3S), malloc(3C), putc(3S), stdio(3S).

# DIAGNOSTICS

If an illegal value for type or size is provided, setvbuf returns a non-zero value. Otherwise, the value returned will be zero.

# NOTES

A common source of error is allocating buffer space as an "automatic" variable in a code block, and then failing to close the stream in the same block.

setjmp, longjmp - non-local goto

## SYNOPSIS

#include <setjmp.h>
int setjmp (env)
jmp\_buf env;
void longjmp (env, val)
jmp\_buf env;
int val;

#### DESCRIPTION

These functions are useful for dealing with errors and interrupts encountered in a low-level subroutine of a program.

Setjmp saves its stack environment in env (whose type, jmp\_buf, is defined in the <setjmp.h> header file) for later use by longjmp. It returns the value 0.

Longjmp restores the environment saved by the last call of setjmp with the corresponding env argument. After longjmp is completed, program execution continues as if the corresponding call of setjmp (which must not itself have returned in the interim) had just returned the value val. Longjmp cannot cause setjmp to return the value 0. If longjmp is invoked with a second argument of 0, setjmp will return 1. All accessible data had values as of the time longjmp was called.

#### SEE ALSO

signal(2).

## WARNING

If *longjmp* is called even though *env* was never primed by a call to *setjmp*, or when the last such call was in a function which has since returned, absolute chaos is guaranteed.

sleep - suspend execution for interval

**SYNOPSIS** 

unsigned sleep (seconds) unsigned seconds;

# DESCRIPTION

The current process is suspended from execution for the number of seconds specified by the argument. The actual suspension time may be less than that requested for two reasons: (1) Because scheduled wakeups occur at fixed 1-second intervals, (on the second, according to an internal clock) and (2) because any caught signal will terminate the sleep following execution of that signal's catching routine. Also, the suspension time may be longer than requested by an arbitrary amount due to the scheduling of other activity in the system. The value returned by sleep will be the "unslept" amount (the requested time minus the time actually slept) in case the caller had an alarm set to go off earlier than the end of the requested sleep time, or premature arousal due to another caught signal.

The routine is implemented by setting an alarm signal and pausing until it (or some other signal) occurs. The previous state of the alarm signal is saved and restored. The calling program may have set up an alarm signal before calling sleep. If the sleep time exceeds the time till such alarm signal, the process sleeps only until the alarm signal would have occurred. The caller's alarm catch routine is executed just before the sleep routine returns. But if the sleep time is less than the time till such alarm, the prior alarm time is reset to go off at the same time it would have without the intervening sleep.

alarm(2), pause(2), signal(2).

ssignal, gsignal - software signals

## **SYNOPSIS**

```
#include <signal.h>
int (*ssignal (sig, action))( )
int sig, (*action)( );
int gsignal (sig)
int sig;
```

## DESCRIPTION

Ssignal and gsignal implement a software facility similar to signal (2). This facility is used by the Standard C Library to enable users to indicate the disposition of error conditions, and is also made available to users for their own purposes.

Software signals made available to users are associated with integers in the inclusive range 1 through 15. A call to *ssignal* associates a procedure, *action*, with the software signal *sig*; the software signal, *sig*, is raised by a call to *gsignal*. Raising a software signal causes the action established for that signal to be *taken*.

The first argument to *ssignal* is a number identifying the type of signal for which an action is to be established. The second argument defines the action; it is either the name of a (user-defined) action function or one of the manifest constants SIG\_DFL (default) or SIG\_IGN (ignore). Ssignal returns the action previously established for that signal type; if no action has been established or the signal number is illegal, ssignal returns SIG\_DFL.

Gsignal raises the signal identified by its argument, sig:

If an action function has been established for sig, then that action is reset to SIG\_DFL and the action function is entered with argument sig. Gsig-nal returns the value returned to it by the action function.

If the action for sig is SIG\_IGN, gsignal returns the value 1 and takes no other action.

If the action for sig is SIG\_DFL, gsignal returns the value 0 and takes no other action.

If sig has an illegal value or no action was ever specified for sig, gsignal returns the value 0 and takes no other action.

## SEE ALSO

signal(2).

#### NOTES

There are some additional signals with numbers outside the range 1 through 15 which are used by the Standard C Library to indicate error conditions. Thus, some signal numbers outside the range 1 through 15 are legal, although their use may interfere with the operation of the Standard C Library.

stdio - standard buffered input/output package

# **SYNOPSIS**

#include <stdio.h>

FILE \*stdin, \*stdout, \*stderr;

## DESCRIPTION

The functions described in the entries of sub-class 3S of this manual constitute an efficient, user-level I/O buffering scheme. The in-line macros getc (3S) and putc (3S) handle characters quickly. The macros getchar and putchar, and the higher-level routines fgetc, fgets, fprintf, fputc, fputs, fread, fscanf, fwrite, gets, getw, printf, puts, putw, and scanf all use or act as if they use getc and putc; they can be freely intermixed.

A file with associated buffering is called a *stream* and is declared to be a pointer to a defined type FILE. *Fopen*(3S) creates certain descriptive data for a stream and returns a pointer to designate the stream in all further transactions. Normally, there are three open streams with constant pointers declared in the <stdio.h> header file and associated with the standard open files:

stdinstandard input filestdoutstandard output filestderrstandard error file

A constant NULL (0) designates a nonexistent pointer.

An integer-constant EOF (-1) is returned upon end-of-file or error by most integer functions that deal with streams (see the individual descriptions for details).

An integer constant BUFSIZ specifies the size of the buffers used by the particular implementation.

Any program that uses this package must include the header file of pertinent macro definitions, as follows:

#### #include <stdio.h>

The functions and constants mentioned in the entries of sub-class 3S of this manual are declared in that header file and need no further declaration. The constants and the following "functions" are implemented as macros (redeclaration of these names is perilous): getc, getchar, putc, putchar, ferror, feof, clearerr, and fileno.

# SEE ALSO

open(2), close(2), lseek(2), pipe(2), read(2), write(2), ctermid(3S), cuserid(3S), fclose(3S), ferror(3S), fopen(3S), fread(3S), fseek(3S), gets(3S), popen(3S), printf(3S), putc(3S), puts(3S), scanf(3S), setbuf(3S), system(3S), tmpfile(3S), tmpnam(3S), ungetc(3S).

# DIAGNOSTICS

Invalid *stream* pointers will usually cause grave disorder, possibly including program termination. Individual function descriptions describe the possible error conditions.

ftok - standard interprocess communication package

## **SYNOPSIS**

```
#include <sys/types.h>
#include <sys/ipc.h>
key_t ftok(path, id)
char *path;
char id;
```

## DESCRIPTION

All interprocess communication facilities require the user to supply a key to be used by the msgget(2), semget(2), and shmget(2) system calls to obtain interprocess communication identifiers. One suggested method for forming a key is to use the ftok subroutine described below. Another way to compose keys is to include the project ID in the most significant byte and to use the remaining portion as a sequence number. There are many other ways to form keys, but it is necessary for each system to define standards for forming them. If some standard is not adhered to, it will be possible for unrelated processes to unintentionally interfere with each other's operation. Therefore, it is strongly suggested that the most significant byte of a key in some sense refer to a project so that keys do not conflict across a given system.

Ftok returns a key based on path and id that is usable in subsequent msgget, semget, and shmget system calls. Path must be the path name of an existing file that is accessible to the process. Id is a character which uniquely identifies a project. Note that ftok will return the same key for linked files when called with the same id and that it will return different keys when called with the same file name but different ids.

## **SEE ALSO**

intro(2), msgget(2), semget(2), shmget(2).

#### DIAGNOSTICS

Ftok returns  $(key_t) -1$  if path does not exist or if it is not accessible to the process.

## WARNING

If the file whose *path* is passed to *ftok* is removed when keys still refer to the file, future calls to *ftok* with the same *path* and *id* will return an error. If the same file is recreated, then *ftok* is likely to return a different key than it did the original time it was called.

streat, strneat, stremp, strnemp, strepy, strnepy, strlen, strehr, strrchr, strpbrk, strspn, strespn, strtok — string operations

## **SYNOPSIS**

```
#include <string.h>
char *strcat (s1, s2)
char *s1, *s2;
char *strncat (s1, s2, n)
char *s1, *s2;
int n;
int strcmp (s1, s2)
char *s1, *s2;
int strncmp (s1, s2, n)
char *s1, *s2;
int n;
char *strcpy (s1, s2)
char *s1, *s2;
char *strncpy (s1, s2, n)
char *s1, *s2;
int n;
int strlen (s)
char *s;
char *strchr (s, c)
char *s;
int c;
char *strrchr (s, c)
char *s;
int c;
char *strpbrk (s1, s2)
char *s1, *s2;
int strspn (s1, s2)
char *s1, *s2;
int strespn (s1, s2)
char *s1, *s2;
char *strtok (s1, s2)
char *s1, *s2;
```

# DESCRIPTION

The arguments s1, s2 and s point to strings (arrays of characters terminated by a null character). The functions *strcat*, *strncat*, *strcpy*, and *strncpy* all alter s1. These functions do not check for overflow of the array pointed to by s1.

Streat appends a copy of string s2 to the end of string s1. Strncat appends at most n characters. Each returns a pointer to the null-terminated result.

Strcmp compares its arguments and returns an integer less than, equal to, or greater than 0, according as s1 is lexicographically less than, equal to, or greater than s2. Strncmp makes the same comparison but looks at at most n characters.

Strcpy copies string s2 to s1, stopping after the null character has been copied. Strncpy copies exactly n characters, truncating s2 or adding null characters to s1 if necessary. The result will not be null-terminated if the length of s2 is n or more. Each function returns s1.

Strlen returns the number of characters in s, not including the terminating null character.

Strchr (strrchr) returns a pointer to the first (last) occurrence of character c in string s, or a NULL pointer if c does not occur in the string. The null character terminating a string is considered to be part of the string.

Strpbrk returns a pointer to the first occurrence in string s1 of any character from string s2, or a NULL pointer if no character from s2 exists in s1.

Strspn (strcspn) returns the length of the initial segment of string s1 which consists entirely of characters from (not from) string s2.

Strtok considers the string s1 to consist of a sequence of zero or more text tokens separated by spans of one or more characters from the separator string s2. The first call (with pointer s1 specified) returns a pointer to the first character of the first token, and will have written a null character into s1 immediately following the returned token. The function keeps track of its position in the string between separate calls, so that subsequent calls (which must be made with the first argument a NULL pointer) will work through the string s1 immediately following that token. In this way subsequent calls will work through the string s1 until no tokens remain. The separator string s2 may be different from call to call. When no token remains in s1, a NULL pointer is returned.

For user convenience, all these functions are declared in the optional <string.h> header file.

#### **BUGS**

Strcmp and strncmp use native character comparison, which is unsigned. Thus the sign of the value returned when one of the characters has its high-order bit set is implementation-dependent.

Character movement is performed differently in different implementations. Thus overlapping moves may yield surprises.

strtod, atof - convert string to double-precision number

# SYNOPSIS

double strtod (str, ptr) char \*str, \*\*ptr; double atof (str) char \*str;

# DESCRIPTION

Strtod returns as a double-precision floating-point number the value represented by the character string pointed to by str. The string is scanned up to the first unrecognized character.

Strtod recognizes an optional string of "white-space" characters (as defined by isspace in ctype(3C)), then an optional sign, then a string of digits optionally containing a decimal point, then an optional e or  $\mathbb{E}$  followed by an optional sign or space, followed by an integer.

If the value of ptr is not (char \*\*) NULL, a pointer to the character terminating the scan is returned in the location pointed to by ptr. If no number can be formed, \*ptr is set to str, and zero is returned.

Atof(str) is equivalent to strtod(str, (char \*\*)NULL).

## SEE ALSO

ctype(3C), scanf(3S), strtol(3C).

# DIAGNOSTICS

If the correct value would cause overflow, ±HUGE is returned (according to the sign of the value), and *errno* is set to ERANGE.

If the correct value would cause underflow, zero is returned and errno is set to ERANGE.

strtol, atol, atoi - convert string to integer

## **SYNOPSIS**

long strtol (str, ptr, base)
char \*str, \*\*ptr;
int base;
long atol (str)
char \*str;
int atoi (str)
char \*str;

## DESCRIPTION

Strtol returns as a long integer the value represented by the character string pointed to by str. The string is scanned up to the first character inconsistent with the base. Leading "white-space" characters (as defined by isspace in ctype(3C)) are ignored.

If the value of ptr is not (char \*\*) NULL, a pointer to the character terminating the scan is returned in the location pointed to by ptr. If no integer can be formed, that location is set to str, and zero is returned.

If base is positive (and not greater than 36), it is used as the base for conversion. After an optional leading sign, leading zeros are ignored, and "0x" or "0X" is ignored if base is 16.

If base is zero, the string itself determines the base thusly: After an optional leading sign a leading zero indicates octal conversion, and a leading "0x" or "0X" hexadecimal conversion. Otherwise, decimal conversion is used.

Truncation from long to int can, of course, take place upon assignment or by an explicit cast.

Atol(str) is equivalent to strtol(str, (char \*\*)NULL, 10).

Atoi(str) is equivalent to (int) strtol(str, (char \*\*)NULL, 10).

# SEE ALSO

ctype(3C), scanf(3S), strtod(3C).

#### **BUGS**

Overflow conditions are ignored.

swab – swap bytes

# SYNOPSIS

void swab (from, to, nbytes)
char \*from, \*to;
int nbytes;

# DESCRIPTION

Swab copies nbytes bytes pointed to by from to the array pointed to by to, exchanging adjacent even and odd bytes. It is useful for carrying binary data between PDP-11s and other machines. Nbytes should be even and nonnegative. If nbytes is odd and positive swab uses nbytes—1 instead. If nbytes is negative, swab does nothing.

system - issue a shell command

# SYNOPSIS

#include <stdio.h>

int system (string)

char \*string;

## DESCRIPTION

System causes the string to be given to sh(1) as input, as if the string had been typed as a command at a terminal. The current process waits until the shell has completed, then returns the exit status of the shell.

## **FILES**

/bin/sh

# SEE ALSO

exec(2).

sh(1) in the 3B2 Computer System User Reference Manual.

## DIAGNOSTICS

System forks to create a child process that in turn exec's /bin/sh in order to execute string. If the fork or exec fails, system returns a negative value and sets errno.

tmpfile - create a temporary file

**SYNOPSIS** 

#include <stdio.h>
FILE \*tmpfile ()

# DESCRIPTION

Tmpfile creates a temporary file using a name generated by tmpnam(3S), and returns a corresponding FILE pointer. If the file cannot be opened, an error message is printed using perror(3C), and a NULL pointer is returned. The file will automatically be deleted when the process using it terminates. The file is opened for update ("w+").

# SEE ALSO

creat(2), unlink(2), fopen(3S), mktemp(3C), perror(3C), tmpnam(3S).

tmpnam, tempnam - create a name for a temporary file

## SYNOPSIS

#include <stdio.h>
char \*tmpnam (s)
char \*s;
char \*tempnam (dir, pfx)
char \*dir, \*pfx;

#### DESCRIPTION

These functions generate file names that can safely be used for a temporary file

Tmpnam always generates a file name using the path-prefix defined as  $P\_tmpdir$  in the <stdio.h> header file. If s is NULL, tmpnam leaves its result in an internal static area and returns a pointer to that area. The next call to tmpnam will destroy the contents of the area. If s is not NULL, it is assumed to be the address of an array of at least  $L\_tmpnam$  bytes, where  $L\_tmpnam$  is a constant defined in <stdio.h>; tmpnam places its result in that array and returns s.

Tempnam allows the user to control the choice of a directory. The argument dir points to the name of the directory in which the file is to be created. If dir is NULL or points to a string which is not a name for an appropriate directory, the path-prefix defined as P\_tmpdir in the <stdio.h> header file is used. If that directory is not accessible, /tmp will be used as a last resort. This entire sequence can be up-staged by providing an environment variable TMPDIR in the user's environment, whose value is the name of the desired temporary-file directory.

Many applications prefer their temporary files to have certain favorite initial letter sequences in their names. Use the pfx argument for this. This argument may be NULL or point to a string of up to five characters to be used as the first few characters of the temporary-file name.

Tempnam uses malloc(3C) to get space for the constructed file name, and returns a pointer to this area. Thus, any pointer value returned from tempnam may serve as an argument to free (see malloc(3C)). If tempnam cannot return the expected result for any reason, i.e. malloc(3C) failed, or none of the above mentioned attempts to find an appropriate directory was successful, a NULL pointer will be returned.

## NOTES

These functions generate a different file name each time they are called.

Files created using these functions and either fopen(3S) or creat(2) are temporary only in the sense that they reside in a directory intended for temporary use, and their names are unique. It is the user's responsibility to use unlink(2) to remove the file when its use is ended.

#### SEE ALSO

creat(2), unlink(2), fopen(3S), malloc(3C), mktemp(3C), tmpfile(3S).

# **BUGS**

If called more than 17,576 times in a single process, these functions will start recycling previously used names.

Between the time a file name is created and the file is opened, it is possible for some other process to create a file with the same name. This can never happen if that other process is using these functions or *mktemp*, and the file names are chosen so as to render duplication by other means unlikely.

tsearch, tfind, tdelete, twalk - manage binary search trees

SYNOPSIS

#include <search.h>
char \*tsearch ((char \*) key, (char \*\*) rootp, compar)
int (\*compar)();
char \*tfind ((char \*) key, (char \*\*) rootp, compar)
int (\*compar)();
char \*tdelete ((char \*) key, (char \*\*) rootp, compar)
int (\*compar)();
void twalk ((char \*) root, action)
void (\*action)();

## DESCRIPTION

Tsearch, tfind, tdelete, and twalk are routines for manipulating binary search trees. They are generalized from Knuth (6.2.2) Algorithms T and D. All comparisons are done with a user-supplied routine. This routine is called with two arguments, the pointers to the elements being compared. It returns an integer less than, equal to, or greater than 0, according to whether the first argument is to be considered less than, equal to or greater than the second argument. The comparison function need not compare every byte, so arbitrary data may be contained in the elements in addition to the values being compared.

Tsearch is used to build and access the tree. Key is a pointer to a datum to be accessed or stored. If there is a datum in the tree equal to \*key (the value pointed to by key), a pointer to this found datum is returned. Otherwise, \*key is inserted, and a pointer to it returned. Only pointers are copied, so the calling routine must store the data. Rootp points to a variable that points to the root of the tree. A NULL value for the variable pointed to by rootp denotes an empty tree; in this case, the variable will be set to point to the datum which will be at the root of the new tree.

Like tsearch, tfind will search for a datum in the tree, returning a pointer to it if found. However, if it is not found, tfind will return a NULL pointer. The arguments for tfind are the same as for tsearch.

Tdelete deletes a node from a binary search tree. The arguments are the same as for tsearch. The variable pointed to by rootp will be changed if the deleted node was the root of the tree. Tdelete returns a pointer to the parent of the deleted node, or a NULL pointer if the node is not found.

Twalk traverses a binary search tree. Root is the root of the tree to be traversed. (Any node in a tree may be used as the root for a walk below that node.) Action is the name of a routine to be invoked at each node. This routine is, in turn, called with three arguments. The first argument is the address of the node being visited. The second argument is a value from an enumeration data type typedef enum { preorder, postorder, endorder, leaf } VISIT; (defined in the <search.h> header file), depending on whether this is the first, second or third time that the node has been visited (during a depth-first, left-to-right traversal of the tree), or whether the node is a leaf. The third argument is the level of the node in the tree, with the root being level zero.

The pointers to the key and the root of the tree should be of type pointer-toelement, and cast to type pointer-to-character. Similarly, although declared as type pointer-to-character, the value returned should be cast into type pointerto-element.

## **EXAMPLE**

The following code reads in strings and stores structures containing a pointer to each string and a count of its length. It then walks the tree, printing out the stored strings and their lengths in alphabetical order.

```
#include <search.h>
#include <stdio.h>
struct node {
                       /* pointers to these are stored in the tree */
        char *string;
        int length;
};
char string space[10000];
                               /* space to store strings */
struct node nodes[500];
                               /* nodes to store */
struct node *root = NULL;
                               /* this points to the root */
main()
        char *strptr = string_space;
        struct node *nodeptr = nodes;
        void print_node( ), twalk( );
        int i = 0, node compare();
        while (gets(strptr) != NULL && i++ < 500) {
                /* set node */
               nodeptr->string = strptr;
               nodeptr->length = strlen(strptr);
               /* put node into the tree */
                (void) tsearch((char *) nodeptr, &root,
                         node compare);
               /* adjust pointers, so we don't overwrite tree */
               strptr += nodeptr -> length + 1;
               nodeptr++;
       twalk(root, print_node);
}
/*
       This routine compares two nodes, based on an
       alphabetical ordering of the string field.
*/
int
node compare(node1, node2)
struct node *node1, *node2;
       return strcmp(node1->string, node2->string);
/*
       This routine prints out a node, the first time
       twalk encounters it.
```

## SEE ALSO

bsearch(3C), hsearch(3C), lsearch(3C).

## **DIAGNOSTICS**

A NULL pointer is returned by tsearch if there is not enough space available to create a new node.

A NULL pointer is returned by tsearch, tfind and tdelete if rootp is NULL on entry.

If the datum is found, both tsearch and tfind return a pointer to it. If not, tfind returns NULL, and tsearch returns a pointer to the inserted item.

# WARNINGS

The **root** argument to *twalk* is one level of indirection less than the **rootp** arguments to *tsearch* and *tdelete*.

There are two nomenclatures used to refer to the order in which tree nodes are visited. *Tsearch* uses preorder, postorder and endorder to respectively refer to visting a node before any of its children, after its left child and before its right, and after both its children. The alternate nomenclature uses preorder, inorder and postorder to refer to the same visits, which could result in some confusion over the meaning of postorder.

#### **BUGS**

If the calling function alters the pointer to the root, results are unpredictable.

ttyname, isatty - find name of a terminal

# **SYNOPSIS**

char \*ttyname (fildes)

int fildes;

int isatty (fildes)

int fildes;

# DESCRIPTION

Ttyname returns a pointer to a string containing the null-terminated path name of the terminal device associated with file descriptor fildes.

Isatty returns 1 if fildes is associated with a terminal device, 0 otherwise.

# **FILES**

/dev/\*

# DIAGNOSTICS

Ttyname returns a NULL pointer if fildes does not describe a terminal device in directory /dev.

## **BUGS**

The return value points to static data whose content is overwritten by each call.

ttyslot - find the slot in the utmp file of the current user

## SYNOPSIS

int ttyslot ()

# **DESCRIPTION**

Ttyslot returns the index of the current user's entry in the /etc/utmp file. This is accomplished by actually scanning the file /etc/inittab for the name of the terminal associated with the standard input, the standard output, or the error output (0, 1 or 2).

# **FILES**

/etc/inittab /etc/utmp

## SEE ALSO

getut(3C), ttyname(3C).

# DIAGNOSTICS

A value of 0 is returned if an error was encountered while searching for the terminal name or if none of the above file descriptors is associated with a terminal device.

ungetc - push character back into input stream

#### **SYNOPSIS**

#include <stdio.h>
int ungetc (c, stream)
int c;
FILE \*stream;

# DESCRIPTION

Ungetc inserts the character c into the buffer associated with an input stream. That character, c, will be returned by the next getc(3S) call on that stream. Ungetc returns c, and leaves the file stream unchanged.

One character of pushback is guaranteed, provided something has already been read from the stream and the stream is actually buffered. In the case that *stream* is *stdin*, one character may be pushed back onto the buffer without a previous read statement.

If c equals EOF, ungetc does nothing to the buffer and returns EOF.

Fseek (3S) erases all memory of inserted characters.

# SEE ALSO

fseek(3S), getc(3S), setbuf(3S).

# DIAGNOSTICS

Ungetc returns EOF if it cannot insert the character.

```
NAME
```

vprintf, vfprintf, vsprintf - print formatted output of a varargs argument list

## **SYNOPSIS**

```
#include <stdio.h>
#include <varargs.h>
int vprintf (format, ap)
char *format;
va_list ap;
int vfprintf (stream, format, ap)
FILE *stream;
char *format;
va_list ap;
int vsprintf (s, format, ap)
char *s, *format;
va list ap;
```

# DESCRIPTION

vprintf, vfprintf, and vsprintf are the same as printf, fprintf, and sprintf respectively, except that instead of being called with a variable number of arguments, they are called with an argument list as defined by varargs (5).

## **EXAMPLE**

The following demonstrates how *vfprintf* could be used to write an error routine.

```
#include <stdio.h>
        #include <varargs.h>
                error should be called like
                        error(function name, format, arg1, arg2...);
         */
        /*VARARGS0*/
        void
        error(va_alist)
        /* Note that the function_name and format arguments cannot be
                separately declared because of the definition of varargs.
         */
        va_dcl
                va list args;
                char *fmt;
                va start(args);
                /* print out name of function causing error */
                (void)fprintf(stderr, "ERROR in %s: ", va_arg(args, char *));
                fmt = va arg(args, char *);

j0, j1, jn, y0, y1, yn - Bessel functions

# **SYNOPSIS**

#include <math.h>

double j0 (x)

double x;

double i1 (x)

double x;

double jn (n, x)

int n;

double x;

double y0 (x)

double x;

double y1 (x)

double x;

double yn (n, x)

int n;

double x;

# DESCRIPTION

J0 and j1 return Bessel functions of x of the first kind of orders 0 and 1 respectively. Jn returns the Bessel function of x of the first kind of order n.

YO and yI return Bessel functions of x of the second kind of orders 0 and 1 respectively. Yn returns the Bessel function of x of the second kind of order n. The value of x must be positive.

## SEE ALSO

matherr(3M).

# DIAGNOSTICS

Non-positive arguments cause y0, y1 and yn to return the value -HUGE and to set errno to EDOM. In addition, a message indicating DOMAIN error is printed on the standard error output.

Arguments too large in magnitude cause j0, j1, y0 and y1 to return zero and to set errno to ERANGE. In addition, a message indicating TLOSS error is printed on the standard error output.

These error-handling procedures may be changed with the function matherr (3M).

erf, erfc - error function and complementary error function

**SYNOPSIS** 

#include <math.h>

double erf (x)

double x;

double erfc (x)

double x;

DESCRIPTION

Erf returns the error function of x, defined as  $\frac{2}{\sqrt{\pi}} \int_{0}^{x} e^{-t^2} dt$ .

Erfc, which returns 1.0 - erf(x), is provided because of the extreme loss of relative accuracy if erf(x) is called for large x and the result subtracted from 1.0 (e.g., for x = 5, 12 places are lost).

SEE ALSO

exp(3M).

10/84

10/84

exp, log, log10, pow, sqrt - exponential, logarithm, power, square root functions

# SYNOPSIS

#include <math.h>

double exp (x)

double x;

double log (x)

double x;

double log10 (x)

double x:

double pow (x, y)

double x, y;

double sqrt (x)

double x:

# DESCRIPTION

Exp returns  $e^{x}$ .

Log returns the natural logarithm of x. The value of x must be positive.

Log 10 returns the logarithm base ten of x. The value of x must be positive.

Pow returns  $x^{y}$ . If x is zero, y must be positive. If x is negative, y must be an integer.

Sqrt returns the non-negative square root of x. The value of x may not be negative.

# SEE ALSO

hypot(3M), matherr(3M), sinh(3M).

### DIAGNOSTICS

Exp returns HUGE when the correct value would overflow, or 0 when the correct value would underflow, and sets errno to ERANGE.

Log and log10 return -HUGE and set *errno* to EDOM when x is non-positive. A message indicating DOMAIN error (or SING error when x is 0) is printed on the standard error output.

Pow returns 0 and sets errno to EDOM when x is 0 and y is non-positive, or when x is negative and y is not an integer. In these cases a message indicating DOMAIN error is printed on the standard error output. When the correct value for pow would overflow or underflow, pow returns  $\pm \text{HUGE}$  or 0 respectively, and sets errno to ERANGE.

Sqrt returns 0 and sets errno to EDOM when x is negative. A message indicating DOMAIN error is printed on the standard error output.

These error-handling procedures may be changed with the function matherr(3M).

floor, ceil, fmod, fabs - floor, ceiling, remainder, absolute value functions

### **SYNOPSIS**

#include <math.h>
double floor (x)
double x;
double ceil (x)
double x;
double fmod (x, y)
double x, y;

double fabs (x) double x;

# DESCRIPTION

Floor returns the largest integer (as a double-precision number) not greater than x.

Ceil returns the smallest integer not less than x.

*Fmod* returns the floating-point remainder of the division of x by y: zero if y is zero or if x/y would overflow; otherwise the number f with the same sign as x, such that x = iy + f for some integer i, and |f| < |y|.

Fabs returns the absolute value of x, |x|.

# SEE ALSO

abs(3C).

10/84

gamma - log gamma function

### **SYNOPSIS**

#include <math.h>

double gamma (x)

double x;

extern int signgam;

# DESCRIPTION

Gamma returns  $\ln(|\Gamma(x)|)$ , where  $\Gamma(x)$  is defined as  $\int_{0}^{\infty} e^{-t} t^{x-1} dt$ . The sign

of  $\Gamma(x)$  is returned in the external integer signgam. The argument x may not be a non-positive integer.

The following C program fragment might be used to calculate  $\Gamma$ :

where LN\_MAXDOUBLE is the least value that causes exp(3M) to return a range error, and is defined in the  $\langle values.h \rangle$  header file.

# SEE ALSO

exp(3M), matherr(3M), values(5).

# DIAGNOSTICS

For non-negative integer arguments HUGE is returned, and *errno* is set to EDOM. A message indicating SING error is printed on the standard error output.

If the correct value would overflow, gamma returns HUGE and sets errno to ERANGE.

These error-handling procedures may be changed with the function mather (3M).

10/84 - 1 - 10/84

hypot - Euclidean distance function

SYNOPSIS

#include <math.h>
double hypot (x, y)
double x, y;

DESCRIPTION

Hypot returns

$$sqrt(x * x + y * y),$$

taking precautions against unwarranted overflows.

# SEE ALSO

matherr(3M).

# DIAGNOSTICS

When the correct value would overflow, hypot returns HUGE and sets errno to ERANGE.

These error-handling procedures may be changed with the function mather (3M).

10/84

matherr - error-handling function

#### SYNOPSIS

```
#include <math.h>
int matherr (x)
struct exception *x;
```

### DESCRIPTION

Matherr is invoked by functions in the Math Library when errors are detected. Users may define their own procedures for handling errors, by including a function named matherr in their programs. Matherr must be of the form described above. When an error occurs, a pointer to the exception structure x will be passed to the user-supplied matherr function. This structure, which is defined in the <math.h> header file, is as follows:

```
struct exception {
    int type;
    char *name;
    double arg1, arg2, retval;
};
```

The element *type* is an integer describing the type of error that has occurred, from the following list of constants (defined in the header file):

```
DOMAIN argument domain error
SING argument singularity
OVERFLOW overflow range error
UNDERFLOW underflow range error
TLOSS total loss of significance
PLOSS partial loss of significance
```

The element *name* points to a string containing the name of the function that incurred the error. The variables argl and arg2 are the arguments with which the function was invoked. *Retval* is set to the default value that will be returned by the function unless the user's *matherr* sets it to a different value.

If the user's *matherr* function returns non-zero, no error message will be printed, and *errno* will not be set.

If matherr is not supplied by the user, the default error-handling procedures, described with the math functions involved, will be invoked upon error. These procedures are also summarized in the table below. In every case, errno is set to EDOM or ERANGE and the program continues.

# **EXAMPLE**

}

DEFAULT ERROR HANDLING PROCEDURES						
	Types of Errors					
type	DOMAIN	SING	OVERFLOW	UNDERFLOW	TLOSS	PLOSS
errno	EDOM	EDOM	ERANGE	ERANGE	ERANGE	ERANGE
BESSEL:	_	=	=	-	M, 0	
y0, y1, yn (arg ≤ 0)	М, -Н		×-	_	-	_
EXP:	_	_	Н	0	_	
LOG, LOG10:						
(arg < 0)	М, -Н	_	_	-	_	
(arg = 0)	-	м, -н	_	_	_	-
POW:	-	-	±Η	0	-	_
neg ** non-int	M, 0	_	_	_	-	
0 ** non-pos						
SQRT:	M, 0	_	_	_	_	
GAMMA:	_	M, H	Н	_	-	
НҮРОТ:	_		Н	_	-	
SINH:	_	=	±Η	-	=	
COSH:		_	Н	-	_	
SIN, COS, TAN: —	_	_	_	M, 0	*	
asin, acos, atan2: M, 0	_	_	_	_		

# **ABBREVIATIONS**

- \* As much as possible of the value is returned.
- M Message is printed (EDOM error).
- H HUGE is returned.
- -H -HUGE is returned.
- ±H HUGE or -HUGE is returned.
- 0 0 is returned.

sinh, cosh, tanh - hyperbolic functions

# SYNOPSIS

#include <math.h>

double sinh (x)

double x;

double cosh (x)

double x;

double tanh (x)

double x;

# DESCRIPTION

Sinh, cosh, and tanh return, respectively, the hyberbolic sine, cosine and tangent of their argument.

# SEE ALSO

matherr(3M).

# DIAGNOSTICS

Sinh and cosh return HUGE (and sinh may return -HUGE for negative x) when the correct value would overflow and set errno to ERANGE.

These error-handling procedures may be changed with the function mather (3M).

10/84

sin, cos, tan, asin, acos, atan, atan2 - trigonometric functions

#### SYNOPSIS

```
#include <math.h>
double sin (x)
double x;
double cos (x)
double x;
double tan (x)
double x;
double asin (x)
double x;
double acos (x)
double x;
double atan (x)
double x;
double atan (x)
double x;
```

# DESCRIPTION

Sin, cos and tan return respectively the sine, cosine and tangent of their argument, x, measured in radians.

Asin returns the arcsine of x, in the range  $-\pi/2$  to  $\pi/2$ .

Acos returns the arccosine of x, in the range 0 to  $\pi$ .

Atan returns the arctangent of x, in the range  $-\pi/2$  to  $\pi/2$ .

Atan2 returns the arctangent of y/x, in the range  $-\pi$  to  $\pi$ , using the signs of both arguments to determine the quadrant of the return value.

### SEE ALSO

matherr(3M).

### DIAGNOSTICS

Sin, cos, and tan lose accuracy when their argument is far from zero. For arguments sufficiently large, these functions return zero when there would otherwise be a complete loss of significance. In this case a message indicating TLOSS error is printed on the standard error output. For less extreme arguments causing partial loss of significance, a PLOSS error is generated but no message is printed. In both cases, errno is set to ERANGE.

If the magnitude of the argument of asin or acos is greater than one, or if both arguments of atan2 are zero, zero is returned and errno is set to EDOM. In addition, a message indicating DOMAIN error is printed on the standard error output.

These error-handling procedures may be changed with the function matherr(3M).

assert - verify program assertion

# SYNOPSIS

#include <assert.h>
assert (expression)
int expression;

### DESCRIPTION

This macro is useful for putting diagnostics into programs. When it is executed, if expression is false (zero), assert prints

"Assertion failed: expression, file xyz, line nnn"

on the standard error output and aborts. In the error message, xyz is the name of the source file and nnn the source line number of the assert statement.

Compiling with the preprocessor option -DNDEBUG (see cpp (1)), or with the preprocessor control statement "#define NDEBUG" ahead of the "#include <assert.h>" statement, will stop assertions from being compiled into the program.

curses - CRT screen handling and optimization package

### **SYNOPSIS**

```
#include < curses.h>
cc [ flags ] files —lcurses [ libraries ]
```

#### DESCRIPTION

These routines give the user a method of updating screens with reasonable optimization. In order to initialize the routines, the routine initscr() must be called before any of the other routines that deal with windows and screens are used. The routine endwin() should be called before exiting. To get characterat-a-time input without echoing, (most interactive, screen oriented-programs want this) after calling initscr() you should call "nonl(); cbreak(); noecho();"

The full curses interface permits manipulation of data structures called windows which can be thought of as two dimensional arrays of characters representing all or part of a CRT screen. A default window called stdscr is supplied, and others can be created with newwin. Windows are referred to by variables declared "WINDOW \*", the type WINDOW is defined in curses.h to be a C structure. These data structures are manipulated with functions described below, among which the most basic are move, and addch. (More general versions of these functions are included with names beginning with 'w', allowing you to specify a window. The routines not beginning with 'w' affect stdscr.) Then refresh() is called, telling the routines to make the users CRT screen look like stdscr.

Mini-Curses is a subset of curses which does not allow manipulation of more than one window. To invoke this subset, use -DMINICURSES as a cc option. This level is smaller and faster than full curses.

If the environment variable TERMINFO is defined, any program using curses will check for a local terminal definition before checking in the standard place. For example, if the standard place is /usr/lib/terminfo, and TERM is set to "vt100", then normally the compiled file is found in /usr/lib/terminfo/v/vt100. (The "v" is copied from the first letter of "vt100" to avoid creation of huge directories.) However, if TERMINFO is set to /usr/mark/myterms, curses will first check /opusr/mark/myterms/v/vt100, and if that fails, will then check /usr/lib/terminfo/v/vt100. This is useful for developing experimental definitions or when write permission in /usr/lib/terminfo is not available.

### TERMINFO LEVEL ROUTINES

These routines should be called by programs wishing to deal directly with the terminfo database. Due to the low level of this interface, it is discouraged. Initially, setupterm should be called. This will define the set of terminal dependent variables defined in terminfo(4). The include files <curses.h> and <term.h> should be included to get the definitions for these strings, numbers, and flags. Parmeterized strings should be passed through tparm to instantiate them. All terminfo strings (including the output of tparm) should be printed with tputs or putp. Before exiting, resetterm should be called to restore the tty modes. (Programs desiring shell escapes or suspending with control Z can call resetterm before the shell is called and fixterm after returning from the shell.)

restore tty modes for terminfo use fixterm()

(called by setupterm)

resetterm()

reset tty modes to state before program entry

setupterm (term, fd, rc)

read in database. Terminal type is the

character string term, all output is to UNIX System file descriptor fd. A status value is returned in the integer pointed to by rc: 1 is normal. The simplest

call would be setupterm(0, 1, 0) which uses all the defaults.

tparm(str, p1, p2, ..., p9)

instantiate string str with parms p; apply padding info to string str.

tputs(str, affent, putc)

affent is the number of lines affected, or 1 if not applicable. Putc is a putchar-like function to which the characters are passed, one at a time. handy function that calls tputs(str, 1, putchar).

vidputs (attrs, putc)

putp(str)

vidattr(attrs)

output the string to put terminal in video attribute mode attrs, which is any combination of the attributes

listed below. Chars are passed to putchar-like function putc.

Like vidputs but outputs through putchar

# TERMCAP COMPATIBILITY ROUTINES

These routines were included as a conversion aid for programs that use termcap. Their parameters are the same as for termcap. They are emulated using the terminfo database. They may go away at a later date.

tgetent(bp, name)

look up termcap entry for name

tgetflag(id) tgetnum (id)

get boolean entry for id get numeric entry for id get string entry for id

tgetstr(id, area) tgoto(cap, col, row)

apply parms to given cap apply padding to cap calling fn as putchar

tputs(cap, affent, fn)

### **ATTRIBUTES**

The following video attributes be passed functions can to the attron, attroff, attrset.

A STANDOUT

Terminal's best highlighting mode

A UNDERLINE A REVERSE A BLINK

Underlining Reverse video Blinking Half bright

A DIM A BOLD

Extra bright or bold

A BLANK

Blanking (invisible)

A PROTECT

Protected

A\_ALTCHARSET

Alternate character set

# **FUNCTION KEYS**

The following function keys might be returned by *getch* if *keypad* has been enabled. Note that not all of these are currently supported, due to lack of definitions in *terminfo* or the terminal not transmitting a unique code when the key is pressed.

key is pressed.		
Name	Value	Key name
KEY_BREAK	0401	break key (unreliable)
KEY_DOWN	0402	The four arrow keys
KEY_UP	0403	
KEY_LEFT	0404	
KEY_RIGHT	0405	
KEY_HOME	0406	Home key (upward+left arrow)
KEY_BACKSPACE	0407	backspace (unreliable)
KEY_F0	0410	Function keys. Space for 64 is reserved.
KEY_F(n)	$(KEY_F0+(n))$	Formula for fn.
KEY_DL	0510	Delete line
KEY_IL	0511	Insert line
KEY_DC	0512	Delete character
KEY_IC	0513	Insert char or enter insert mode
KEY_EIC	0514	Exit insert char mode
KEY_CLEAR	0515	Clear screen
KEY_EOS	0516	Clear to end of screen
KEY_EOL	0517	Clear to end of line
KEY_SF	0520	Scroll 1 line forward
KEY_SR	0521	Scroll 1 line backwards (reverse)
KEY_NPAGE	0522	Next page
KEY_PPAGE	0523	Previous page
KEY_STAB	0524	Set tab
KEY_CTAB	0525	Clear tab
KEY_CATAB	0526	Clear all tabs
KEY_ENTER	0527	Enter or send (unreliable)
KEY_SRESET	0530	soft (partial) reset (unreliable)
KEY_RESET	0531	reset or hard reset (unreliable)
KEY_PRINT	0532	print or copy
KEY_LL	0533	home down or bottom (lower left)

# WARNING

The plotting library plot(3X) and the curses library curses(3X) both use the names erase() and move(). The curses versions are macros. If you need both libraries, put the plot(3X) code in a different source file than the curses(3X) code, and/or #undef move() and erase() in the plot(3X) code.

ldahread - read the archive header of a member of an archive file

# **SYNOPSIS**

#include <stdio.h>
#include <ar.h>
#include <filehdr.h>
#include <ldfcn.h>

int ldahread (ldptr, arhead) LDFILE \*ldptr; ARCHDR \*arhead;

### DESCRIPTION

If TYPE(ldptr) is the archive file magic number, ldahread reads the archive header of the common object file currently associated with ldptr into the area of memory beginning at arhead.

Ldahread returns SUCCESS or FAILURE. Ldahread will fail if TYPE(ldptr) does not represent an archive file, or if it cannot read the archive header.

The program must be loaded with the object file access routine library libld.a.

# SEE ALSO

ldclose(3X), ldopen(3X), ldfcn(4), ar(4).

ldclose, ldaclose - close a common object file

### SYNOPSIS

#include <stdio.h> #include <filehdr.h> #include <ldfcn.h>

int ldclose (ldptr)
LDFILE \*ldptr;
int ldaclose (ldptr)
LDFILE \*ldptr;

### DESCRIPTION

Ldopen(3X) and ldclose are designed to provide uniform access to both simple object files and object files that are members of archive files. Thus an archive of common object files can be processed as if it were a series of simple common object files.

If TYPE(ldptr) does not represent an archive file, ldclose will close the file and free the memory allocated to the LDFILE structure associated with ldptr. If TYPE(ldptr) is the magic number of an archive file, and if there are any more files in the archive, ldclose will reinitialize OFFSET(ldptr) to the file address of the next archive member and return FAILURE. The LDFILE structure is prepared for a subsequent ldopen(3X). In all other cases, ldclose returns SUCCESS.

Ldaclose closes the file and frees the memory allocated to the LDFILE structure associated with *ldptr* regardless of the value of TYPE(*ldptr*). Ldaclose always returns SUCCESS. The function is often used in conjunction with *ldaopen*.

The program must be loaded with the object file access routine library libld.a.

### SEE ALSO

fclose(3S), ldopen(3X), ldfcn(4).

ldfhread - read the file header of a common object file

# **SYNOPSIS**

#include <stdio.h>
#include <filehdr.h>
#include <ldfcn.h>

int ldfhread (ldptr, filehead) LDFILE \*ldptr; FILHDR \*filehead;

### DESCRIPTION

Ldfhread reads the file header of the common object file currently associated with ldptr into the area of memory beginning at filehead.

Ldfhread returns SUCCESS or FAILURE. Ldfhread will fail if it cannot read the file header.

In most cases the use of *ldfhread* can be avoided by using the macro HEADER(*ldptr*) defined in *ldfcn.h* (see ldfcn (4)). The information in any field, *fieldname*, of the file header may be accessed using HEADER(*ldptr*).fieldname.

The program must be loaded with the object file access routine library libld.a.

# SEE ALSO

ldclose(3X), ldopen(3X), ldfcn(4).

ldgetname - retrieve symbol name for common object file symbol table entry

#### SYNOPSIS

#include <stdio.h>
#include <filehdr.h>
#include <syms.h>
#include <ldfcn.h>
char \*ldgetname (ldptr, symbol)
LDFILE \*ldptr;
SYMENT \*symbol;

### DESCRIPTION

Ldgetname returns a pointer to the name associated with symbol as a string. The string is contained in a static buffer local to ldgetname that is overwritten by each call to ldgetname, and therefore must be copied by the caller if the name is to be saved.

As of UNIX System V Release 2.0, the common object file format has been extended to handle arbitrary length symbol names with the addition of a "string table". Ldgetname will return the symbol name associated with a symbol table entry for either a pre-UNIX System V Release 2.0 object file or a UNIX System V Release 2.0 object file. Thus, ldgetname can be used to retrieve names from object files without any backward compatibility problems. Ldgetname will return NULL (defined in stdio.h) for an object file if the name cannot be retrieved. This situation can occur:

- if the "string table" cannot be found,
- if not enough memory can be allocated for the string table,
- if the string table appears not to be a string table (for example, if an auxiliary entry is handed to *ldgetname* that looks like a reference to a name in a non-existent string table), or
- if the name's offset into the string table is past the end of the string table.

Typically, *ldgetname* will be called immediately after a successful call to *ldtbread* to retrieve the name associated with the symbol table entry filled by *ldtbread*.

The program must be loaded with the object file access routine library libld.a.

ldlread, ldlinit, ldlitem - manipulate line number entries of a common object file function

### SYNOPSIS

```
#include <stdio.h>
#include <filehdr.h>
#include linenum.h>
#include <ldfcn.h>

int Idlread(Idntr. fenind
```

int ldlread(ldptr, fcnindx, linenum, linent)
LDFILE \*ldptr;
long fcnindx;
unsigned short linenum;
LINENO linent;
int ldlinit(ldptr, fcnindx)
LDFILE \*ldptr;
long fcnindx;
int ldlitem(ldptr, linenum, linent)
LDFILE \*ldptr;
unsigned short linenum;

#### DESCRIPTION

LINENO linent;

Ldlread searches the line number entries of the common object file currently associated with ldptr. Ldlread begins its search with the line number entry for the beginning of a function and confines its search to the line numbers associated with a single function. The function is identified by fcnindx, the index of its entry in the object file symbol table. Ldlread reads the entry with the smallest line number equal to or greater than linenum into linent.

Ldlinit and ldlitem together perform exactly the same function as ldlread. After an initial call to ldlread or ldlinit, ldlitem may be used to retrieve a series of line number entries associated with a single function. Ldlinit simply locates the line number entries for the function identified by fcnindx. Ldlitem finds and reads the entry with the smallest line number equal to or greater than linenum into linent.

Ldlread, ldlinit, and ldlitem each return either SUCCESS or FAILURE. Ldlread will fail if there are no line number entries in the object file, if fcnindx does not index a function entry in the symbol table, or if it finds no line number equal to or greater than linenum. Ldlinit will fail if there are no line number entries in the object file or if fcnindx does not index a function entry in the symbol table. Ldlitem will fail if tinds no line number equal to or greater than linenum.

The programs must be loaded with the object file access routine library libld.a.

### SEE ALSO

ldclose(3X), ldopen(3X), ldtbindex(3X), ldfcn(4).

ldlseek, ldnlseek - seek to line number entries of a section of a common object file

### **SYNOPSIS**

#include <stdio.h>
#include <filehdr.h>
#include <ldfcn.h>
int ldlseek (ldptr, sectindx)
LDFILE \*ldptr;
unsigned short sectindx;
int ldnlseek (ldptr, sectname)
LDFILE \*ldptr;
char \*sectname;

### DESCRIPTION

Ldlseek seeks to the line number entries of the section specified by sectindx of the common object file currently associated with ldptr.

Ldnlseek seeks to the line number entries of the section specified by sectname.

Ldlseek and ldnlseek return SUCCESS or FAILURE. Ldlseek will fail if sectindx is greater than the number of sections in the object file; ldnlseek will fail if there is no section name corresponding with \*sectname. Either function will fail if the specified section has no line number entries or if it cannot seek to the specified line number entries.

Note that the first section has an index of one.

The program must be loaded with the object file access routine library libld.a.

#### SEE ALSO

ldclose(3X), ldopen(3X), ldshread(3X), ldfcn(4).

ldohseek - seek to the optional file header of a common object file

### **SYNOPSIS**

#include <stdio.h> #include <filehdr.h> #include <ldfcn.h> int ldohseek (ldptr) LDFILE \*ldptr;

### DESCRIPTION

Ldohseek seeks to the optional file header of the common object file currently associated with ldptr.

Ldohseek returns SUCCESS or FAILURE. Ldohseek will fail if the object file has no optional header or if it cannot seek to the optional header.

The program must be loaded with the object file access routine library libld.a.

# SEE ALSO

ldclose(3X), ldopen(3X), ldfhread(3X), ldfcn(4).

ldopen, ldaopen - open a common object file for reading

### **SYNOPSIS**

```
#include <stdio.h>
#include <filehdr.h>
#include <ldfcn.h>

LDFILE *ldopen (filename, ldptr)
char *filename;
LDFILE *ldaopen (filename, oldptr)
char *filename;
LDFILE *ldaopen (filename, oldptr)
char *filename;
LDFILE *oldptr;
```

# **DESCRIPTION**

Ldopen and ldclose (3X) are designed to provide uniform access to both simple object files and object files that are members of archive files. Thus an archive of common object files can be processed as if it were a series of simple common object files.

If *ldptr* has the value NULL, then *ldopen* will open *filename* and allocate and initialize the LDFILE structure, and return a pointer to the structure to the calling program.

If *ldptr* is valid and if TYPE(*ldptr*) is the archive magic number, *ldopen* will reinitialize the LDFILE structure for the next archive member of *filename*.

Ldopen and ldclose (3X) are designed to work in concert. Ldclose will return FAILURE only when TYPE(ldptr) is the archive magic number and there is another file in the archive to be processed. Only then should ldopen be called with the current value of ldptr. In all other cases, in particular whenever a new filename is opened, ldopen should be called with a NULL ldptr argument.

The following is a prototype for the use of *ldopen* and *ldclose* (3X).

If the value of *oldptr* is not NULL, *ldaopen* will open *filename* anew and allocate and initialize a new LDFILE structure, copying the TYPE, OFFSET, and HEADER fields from *oldptr*. Ldaopen returns a pointer to the new LDFILE structure. This new pointer is independent of the old pointer, *oldptr*. The two pointers may be used concurrently to read separate parts of the object file. For example, one pointer may be used to step sequentially through the relocation information, while the other is used to read indexed symbol table entries.

Both *Idopen* and *Idopen* open *filename* for reading. Both functions return NULL if *filename* cannot be opened, or if memory for the LDFILE structure cannot be allocated. A successful open does not insure that the given file is a common object file or an archived object file.

The program must be loaded with the object file access routine library libld.a.

SEE ALSO

fopen(3S), ldclose(3X), ldfcn(4).

ldrseek, ldnrseek - seek to relocation entries of a section of a common object file

### **SYNOPSIS**

#include <stdio.h>
#include <filehdr.h>
#include <ldfcn.h>
int ldrseek (ldptr, sectindx)
LDFILE \*ldptr;
unsigned short sectindx;
int ldnrseek (ldptr, sectname)
LDFILE \*ldptr;

char \*sectname;

### DESCRIPTION

Ldrseek seeks to the relocation entries of the section specified by sectindx of the common object file currently associated with ldptr.

Ldnrseek seeks to the relocation entries of the section specified by sectname.

Ldrseek and ldnrseek return SUCCESS or FAILURE. Ldrseek will fail if sectindx is greater than the number of sections in the object file; ldnrseek will fail if there is no section name corresponding with sectname. Either function will fail if the specified section has no relocation entries or if it cannot seek to the specified relocation entries.

Note that the first section has an index of one.

The program must be loaded with the object file access routine library libld.a.

#### SEE ALSO

ldclose(3X), ldopen(3X), ldshread(3X), ldfcn(4).

- 1 -

ldshread, ldnshread - read an indexed/named section header of a common object file

### **SYNOPSIS**

#include <stdio.h>
#include <filehdr.h>
#include <scnhdr.h>
#include <ldfcn.h>
int ldshread (ldptr, sectindx, secthead)
LDFILE \*ldptr;
unsigned short sectindx;
SCNHDR \*secthead;
int ldnshread (ldptr, sectname, secthead)
LDFILE \*ldptr;
char \*sectname;
SCNHDR \*secthead;

### DESCRIPTION

Ldshread reads the section header specified by sectindx of the common object file currently associated with ldptr into the area of memory beginning at secthead.

Ldnshread reads the section header specified by sectname into the area of memory beginning at secthead.

Ldshread and ldnshread return SUCCESS or FAILURE. Ldshread will fail if sectindx is greater than the number of sections in the object file; ldnshread will fail if there is no section name corresponding with sectname. Either function will fail if it cannot read the specified section header.

Note that the first section header has an index of one.

The program must be loaded with the object file access routine library libld.a.

# SEE ALSO

Idclose(3X), Idopen(3X), Idfcn(4).

ldsseek, ldnsseek - seek to an indexed/named section of a common object file

### **SYNOPSIS**

#include <stdio.h>
#include <filehdr.h>
#include <filehdr.h>
#include <ldfcn.h>
int ldsseek (ldptr, sectindx)
LDFILE \*ldptr;
unsigned short sectindx;
int ldnsseek (ldptr, sectname)
LDFILE \*ldptr;
char \*sectname;

### DESCRIPTION

Ldsseek seeks to the section specified by sectindx of the common object file currently associated with ldptr.

Ldnsseek seeks to the section specified by sectname.

Ldsseek and ldnsseek return SUCCESS or FAILURE. Ldsseek will fail if sectindx is greater than the number of sections in the object file; ldnsseek will fail if there is no section name corresponding with sectname. Either function will fail if there is no section data for the specified section or if it cannot seek to the specified section.

Note that the first section has an index of one.

The program must be loaded with the object file access routine library libld.a.

#### SEE ALSO

ldclose(3X), ldopen(3X), ldshread(3X), ldfcn(4).

ldtbindex - compute the index of a symbol table entry of a common object file

# SYNOPSIS

#include <stdio.h>
#include <filehdr.h>
#include <syms.h>
#include <ldfcn.h>
long ldtbindex (ldptr)
LDFILE \*ldptr;

# **DESCRIPTION**

Ldtbindex returns the (long) index of the symbol table entry at the current position of the common object file associated with ldptr.

The index returned by *ldtbindex* may be used in subsequent calls to *ldtbread* (3X). However, since *ldtbindex* returns the index of the symbol table entry that begins at the current position of the object file, if *ldtbindex* is called immediately after a particular symbol table entry has been read, it will return the index of the next entry.

Ldtbindex will fail if there are no symbols in the object file, or if the object file is not positioned at the beginning of a symbol table entry.

Note that the first symbol in the symbol table has an index of zero.

The program must be loaded with the object file access routine library libld.a.

# SEE ALSO

ldclose(3X), ldopen(3X), ldtbread(3X), ldtbseek(3X), ldfcn(4).

10/84

ldtbread - read an indexed symbol table entry of a common object file

### **SYNOPSIS**

```
#include <stdio.h>
#include <filehdr.h>
#include <syms.h>
#include <ldfcn.h>
int ldtbread (ldptr, symindex, symbol)
LDFILE *ldptr;
long symindex;
SYMENT *symbol;
```

# DESCRIPTION

Ldtbread reads the symbol table entry specified by symindex of the common object file currently associated with ldptr into the area of memory beginning at symbol.

Ldtbread returns SUCCESS or FAILURE. Ldtbread will fail if symindex is greater than the number of symbols in the object file, or if it cannot read the specified symbol table entry.

Note that the first symbol in the symbol table has an index of zero.

The program must be loaded with the object file access routine library libld.a.

# SEE ALSO

ldclose(3X), ldopen(3X), ldtbseek(3X), ldgetname(3X), ldfcn(4).

10/84

ldtbseek - seek to the symbol table of a common object file

# **SYNOPSIS**

#include <stdio.h> #include <filehdr.h> #include <ldfcn.h> int ldtbseek (ldptr) LDFILE \*ldptr;

# DESCRIPTION

Ldtbseek seeks to the symbol table of the object file currently associated with ldntr

Ldtbseek returns SUCCESS or FAILURE. Ldtbseek will fail if the symbol table has been stripped from the object file, or if it cannot seek to the symbol table.

The program must be loaded with the object file access routine library libld.a.

### SEE ALSO

logname - return login name of user

# SYNOPSIS

char \*logname()

# DESCRIPTION

Logname returns a pointer to the null-terminated login name; it extracts the \$LOGNAME variable from the user's environment.

This routine is kept in /lib/libPW.a.

# **FILES**

/etc/profile

# SEE ALSO

profile(4), environ(5).

env(1), login(1) in the 3B2 Computer System User Reference Manual.

# **BUGS**

The return values point to static data whose content is overwritten by each call.

This method of determining a login name is subject to forgery.

malloc, free, realloc, calloc, mallopt, mallinfo - fast main memory allocator

# SYNOPSIS

#include <malloc.h>
char \*malloc (size)
unsigned size;
void free (ptr)
char \*ptr;
char \*realloc (ptr, size)
char \*ptr;
unsigned size;
char \*calloc (nelem, elsize)
unsigned nelem, elsize;
int mallopt (cmd, value)
int cmd, value;
struct mallinfo mallinfo (max)

#### DESCRIPTION

int max;

Malloc and free provide a simple general-purpose memory allocation package, which runs considerably faster than the malloc(3C) package. It is found in the library "malloc", and is loaded if the option "-lmalloc" is used with cc(1) or ld(1).

Malloc returns a pointer to a block of at least size bytes suitably aligned for any use.

The argument to *free* is a pointer to a block previously allocated by *malloc*; after *free* is performed this space is made available for further allocation, and its contents have been destroyed (but see *mallopt* below for a way to change this behavior).

Undefined results will occur if the space assigned by malloc is overrun or if some random number is handed to free.

Realloc changes the size of the block pointed to by ptr to size bytes and returns a pointer to the (possibly moved) block. The contents will be unchanged up to the lesser of the new and old sizes.

Calloc allocates space for an array of nelem elements of size elsize. The space is initialized to zeros.

Mallopt provides for control over the allocation algorithm. The available values for cmd are:

M\_MXFAST Set maxfast to value. The algorithm allocates all blocks below the size of maxfast in large groups and then doles them out very quickly. The default value for maxfast is 0.

M\_NLBLKS Set numlblks to value. The above mentioned "large groups" each contain numlblks blocks. Numlblks must be greater than 0. The default value for numlblks is 100.

M\_GRAIN Set grain to value. The sizes of all blocks smaller than max-fast are considered to be rounded up to the nearest multiple of grain. Grain must be greater than 0. The default value of grain is the smallest number of bytes which will allow alignment of any data type. Value will be rounded up to a multiple of the default when grain is set.

M KEEP

Preserve data in a freed block until the next *malloc*, *realloc*, or *calloc*. This option is provided only for compatibility with the old version of *malloc* and is not recommended.

These values are defined in the < malloc.h > header file.

Mallopt may be called repeatedly, but may not be called after the first small block is allocated.

Mallinfo provides instrumentation describing space usage. It returns the structure:

```
struct mallinfo {
      int arena:
                         /* total space in arena */
                         /* number of ordinary blocks */
      int ordblks:
      int smblks;
                         /* number of small blocks */
      int hblkhd;
                         /* space in holding block headers */
      int hblks;
                         /* number of holding blocks */
      int usmblks;
                         /* space in small blocks in use */
      int fsmblks;
                         /* space in free small blocks */
                         /* space in ordinary blocks in use */
      int uordblks;
      int fordblks;
                         /* space in free ordinary blocks */
                         /* space penalty if keep option */
      int keepcost;
                         /* is used */
```

This structure is defined in the < malloc, h > header file.

Each of the allocation routines returns a pointer to space suitably aligned (after possible pointer coercion) for storage of any type of object.

brk(2), malloc(3C).

### DIAGNOSTICS

Malloc, realloc and calloc return a NULL pointer if there is not enough available memory. When realloc returns NULL, the block pointed to by ptr is left intact. If mallopt is called after any allocation or if cmd or value are invalid, non-zero is returned. Otherwise, it returns zero.

# WARNINGS

This package usually uses more data space than malloc (3C).

The code size is also bigger than malloc (3C).

Note that unlike malloc(3C), this package does not preserve the contents of a block when it is freed, unless the M\_KEEP option of mallopt is used. Undocumented features of malloc(3C) have not been duplicated.

```
plot - graphics interface subroutines
SYNOPSIS
        openpl ()
        erase ()
        label (s)
        char *s;
        line (x1, y1, x2, y2)
        int x1, y1, x2, y2;
        circle (x, y, r)
        int x, y, r;
        arc (x, y, x0, y0, x1, y1)
        int x, y, x0, y0, x1, y1;
        move (x, y)
        int x, y;
        cont (x, y)
        int x, y;
        point (x, y)
        int x, y;
        linemod (s)
        char *s;
        space (x0, y0, x1, y1)
        int x0, y0, x1, y1;
```

# DESCRIPTION

closepl ()

These subroutines generate graphic output in a relatively device-independent manner. Space must be used before any of these functions to declare the amount of space necessary. See plot (4). Openpl must be used before any of the others to open the device for writing. Closepl flushes the output.

Circle draws a circle of radius r with center at the point (x, y).

Arc draws an arc of a circle with center at the point (x, y) between the points (x0, y0) and (x1, y1).

String arguments to label and linemod are terminated by nulls and do not contain new-lines.

See plot (4) for a description of the effect of the remaining functions.

The library files listed below provide several flavors of these routines.

### **FILES**

/usr/lib/libplot.a	produces output for tplot (1G) filters
/usr/lib/lib300.a	for DASI 300
/usr/lib/lib300s.a	for DASI 300s
/usr/lib/lib450.a	for DASI 450
/usr/lib/lib4014.a	for TEKTRONIX 4014

# SEE ALSO

plot(4).

graph(1G), stat(1G), tplot(1G) in the 3B2 Computer System Graphics Utilities Guide.

### WARNINGS

In order to compile a program containing these functions in *file.c* it is necessary to use "cc *file.c* —lplot".

In order to execute it, it is necessary to use "a.out | tplot".

The above routines use <stdio.h>, which causes them to increase the size of programs, not otherwise using standard I/O, more than might be expected.

regcmp, regex - compile and execute regular expression

### **SYNOPSIS**

```
char *regcmp (string1 [, string2, ...], (char *)0) char *string1, *string2, ...; char *regex (re, subject[, ret0, ...]) char *re, *subject, *ret0, ...; extern char * loc1;
```

#### DESCRIPTION

Regcmp compiles a regular expression and returns a pointer to the compiled form. Malloc(3C) is used to create space for the vector. It is the user's responsibility to free unneeded space so allocated. A NULL return from regcmp indicates an incorrect argument. Regcmp(1) has been written to generally preclude the need for this routine at execution time.

Regex executes a compiled pattern against the subject string. Additional arguments are passed to receive values back. Regex returns NULL on failure or a pointer to the next unmatched character on success. A global character pointer  $\_loc1$  points to where the match began. Regcmp and regex were mostly borrowed from the editor, ed(1); however, the syntax and semantics have been changed slightly. The following are the valid symbols and their associated meanings.

- []\*.^ These symbols retain their current meaning.
- \$ Matches the end of the string; \n matches a new-line.
- Within brackets the minus means through. For example, [a-z] is equivalent to [abcd...xyz]. The can appear as itself only if used as the first or last character. For example, the character class expression [1-] matches the characters ] and -.
- + A regular expression followed by + means one or more times. For example, [0-9] + is equivalent to [0-9][0-9]\*.

# {m} {m,} {m,u}

Integer values enclosed in  $\{\}$  indicate the number of times the preceding regular expression is to be applied. The value m is the minimum number and u is a number, less than 256, which is the maximum. If only m is present (e.g.,  $\{m\}$ ), it indicates the exact number of times the regular expression is to be applied. The value  $\{m,\}$  is analogous to  $\{m,\inf nity\}$ . The plus  $\{+\}$  and star  $\{+\}$  operations are equivalent to  $\{1,\}$  and  $\{0,\}$  respectively.

# (...)\$n

The value of the enclosed regular expression is to be returned. The value will be stored in the (n+1)th argument following the subject argument. At most ten enclosed regular expressions are allowed. Regex makes its assignments unconditionally.

(...) Parentheses are used for grouping. An operator, e.g., \*, +, {}, can work on a single character or a regular expression enclosed in parentheses. For example, (a\*(cb+)\*)\$0.

By necessity, all the above defined symbols are special. They must, therefore, be escaped to be used as themselves.

### **EXAMPLES**

This example will match a leading new-line in the subject string pointed at by cursor.

```
Example 2:
```

```
char ret0[9];
char *newcursor, *name;
...
name = regcmp("([A-Za-z][A-za-z0-9_]{0,7})$0", 0);
newcursor = regex(name, "123Testing321", ret0);
```

This example will match through the string "Testing3" and will return the address of the character after the last matched character (cursor+11). The string "Testing3" will be copied to the character array ret0.

# Example 3:

```
#include "file.i"
char *string, *newcursor;
...
newcursor = regex(name, string);
```

This example applies a precompiled regular expression in file.i (see regcmp(1)) against string.

This routine is kept in /lib/libPW.a.

### SEE ALSO

```
malloc(3C). ed(1) in the 3B2 Computer System User Reference Manual. regcmp(1) in the 3B2 Computer System C Programming Language Utilities.
```

# BUGS

The user program may run out of memory if *regcmp* is called iteratively without freeing the vectors no longer required. The following user-supplied replacement for *malloc*(3C) reuses the same vector saving time and space:

```
/* user's program */
...
char *
malloc(n)
unsigned n;
{
    static char rebuf[512];
    return (n <= sizeof rebuf) ? rebuf : NULL;
}</pre>
```

sputl, sgetl - access long integer data in a machine-independent fashion.

## **SYNOPSIS**

void sputl (value, buffer) long value; char \*buffer; long sgetl (buffer) char \*buffer;

## DESCRIPTION

Sputl takes the four bytes of the long integer value and places them in memory starting at the address pointed to by buffer. The ordering of the bytes is the same across all machines.

Sgetl retrieves the four bytes in memory starting at the address pointed to by buffer and returns the long integer value in the byte ordering of the host machine.

The combination of *sputl* and *sgetl* provides a machine-independent way of storing long numeric data in a file in binary form without conversion to characters.

A program which uses these functions must be loaded with the object-file access routine library libld.a.

```
NAME
```

vprintf, vfprintf, vsprintf - print formatted output of a varargs argument list

```
SYNOPSIS
```

```
#include <stdio.h>
#include <varargs.h>
int vprintf (format, ap)
char *format;
va_list ap;
int vfprintf (stream, format, ap)
FILE *stream;
char *format;
va_list ap;
int vsprintf (s, format, ap)
char *s, *format;
va_list ap;
```

## DESCRIPTION

vprintf, vfprintf, and vsprintf are the same as printf, fprintf, and sprintf respectively, except that instead of being called with a variable number of arguments, they are called with an argument list as defined by varargs (5).

### **EXAMPLE**

The following demonstrates how *vfprintf* could be used to write an error routine.

```
#include <stdio.h>
        #include <varargs.h>
        /*
                error should be called like
                        error(function name, format, arg1, arg2...);
        /*VARARGS0*/
       void
       error(va alist)
        /* Note that the function name and format arguments cannot be
                separately declared because of the definition of varargs.
         */
       va dcl
                va list args;
                char *fmt;
                va start(args);
                /* print out name of function causing error */
                (void)fprintf(stderr, "ERROR in %s: ", va_arg(args, char *));
                fmt = va arg(args, char *);
                /* print out remainder of message */
                (void)vfprintf(fmt, args);
                va end(args);
                (void)abort();
       }
SEE ALSO
       printf(3S), varargs(5).
```

10/84

NAME

abort - terminate Fortran program

## **SYNOPSIS**

call abort ()

## DESCRIPTION

Abort terminates the program which calls it, closing all open files truncated to the current position of the file pointer. The abort usually results in a core dump.

# DIAGNOSTICS

When invoked, abort prints "Fortran abort routine called" on the standard error output. The message "abort - core dumped" is sent to the terminal.

# SEE ALSO

abort(3C).

abs, iabs, dabs, cabs, zabs - Fortran absolute value

#### **SYNOPSIS**

integer i1, i2
real r1, r2
double precision dp1, dp2
complex cx1, cx2
double complex dx1, dx2
r2 = abs(r1)
i2 = iabs(i1)
i2 = abs(i1)
dp2 = dabs(dp1)
dp2 = abs(dp1)
cx2 = cabs(cx1)
cx2 = abs(cx1)
dx2 = zabs(dx1)

dx2 = abs(dx1)

### DESCRIPTION

Abs is the family of absolute value functions. Iabs returns the integer absolute value of its integer argument. Dabs returns the double-precision absolute value of its double-precision argument. Cabs returns the complex absolute value of its complex argument. Zabs returns the double-complex absolute value of its double-complex argument. The generic form abs returns the type of its argument.

## SEE ALSO

floor(3M).

## NAME

acos, dacos - Fortran arccosine intrinsic function

# **SYNOPSIS**

real r1, r2 double precision dp1, dp2 r2 = acos(r1) dp2 = dacos(dp1) dp2 = acos(dp1)

# DESCRIPTION

Acos returns the real arccosine of its real argument. Dacos returns the double-precision arccosine of its double-precision argument. The generic form acos may be used with impunity as its argument will determine the type of the returned value.

# SEE ALSO

aimag, dimag - Fortran imaginary part of complex argument

# SYNOPSIS

real r
complex cxr
double precision dp
double complex cxd
r = aimag(cxr)
dp = dimag(cxd)

# **DESCRIPTION**

Aimag returns the imaginary part of its single-precision complex argument. Dimag returns the double-precision imaginary part of its double-complex argument.

10/84 - 1 - 10/84

10/84

**NAME** 

aint, dint - Fortran integer part intrinsic function

# **SYNOPSIS**

real r1, r2 double precision dp1, dp2 r2 = aint(r1) dp2 = dint(dp1) dp2 = aint(dp1)

# DESCRIPTION

Aint returns the truncated value of its real argument in a real. Dint returns the truncated value of its double-precision argument as a double-precision value. Aint may be used as a generic function name, returning either a real or double-precision value depending on the type of its argument.

asin, dasin - Fortran arcsine intrinsic function

## **SYNOPSIS**

real r1, r2 double precision dp1, dp2 r2 = asin(r1) dp2 = dasin(dp1) dp2 = asin(dp1)

## **DESCRIPTION**

Asin returns the real arcsine of its real argument. Dasin returns the double-precision arcsine of its double-precision argument. The generic form asin may be used with impunity as it derives its type from that of its argument.

## SEE ALSO

atan, datan - Fortran arctangent intrinsic function

## **SYNOPSIS**

real r1, r2 double precision dp1, dp2 r2 = atan(r1) dp2 = datan(dp1) dp2 = atan(dp1)

# **DESCRIPTION**

Atan returns the real arctangent of its real argument. Datan returns the double-precision arctangent of its double-precision argument. The generic form atan may be used with a double-precision argument returning a double-precision value.

# SEE ALSO

atan2, datan2 - Fortran arctangent intrinsic function

# **SYNOPSIS**

real r1, r2, r3
double precision dp1, dp2, dp3
r3 = atan2(r1, r2)
dp3 = datan2(dp1, dp2)
dp3 = atan2(dp1, dp2)

## **DESCRIPTION**

Atan2 returns the arctangent of argllarg2 as a real value. Datan2 returns the double-precision arctangent of its double-precision arguments. The generic form atan2 may be used with impunity with double-precision arguments.

# SEE ALSO

and, or, xor, not, Ishift, rshift - Fortran Bitwise Boolean functions

## **SYNOPSIS**

```
integer i, j, k

real a, b, c

k = and(i, j)

c = or(a, b)

j = xor(i, a)

j = not(i)

k = lshift(i, j)

k = rshift(i, j)
```

# DESCRIPTION

The generic intrinsic Boolean functions and, or and xor return the value of the binary operations on their arguments. Not is a unary operator returning the one's complement of its argument. Lshift and rshift return the value of the first argument shifted left or right, respectively, the number of times specified by the second (integer) argument.

The Boolean functions are generic; that is, they are defined for all data types as arguments and return values. Where required, the compiler will generate appropriate type conversions.

#### NOTE

Although defined for all data types, use of Boolean functions on any but integer data is bizarre and will probably result in unexpected consequences.

## **BUGS**

The implementation of the shift functions may cause large shift values to deliver weird results.

### SEE ALSO

mil(3F).

conjg, dconjg - Fortran complex conjugate intrinsic function

# SYNOPSIS

complex cx1, cx2 double complex dx1, dx2 cx2 = conjg(cx1) dx2 = dconjg(dx1)

# DESCRIPTION

Conjg returns the complex conjugate of its complex argument. Dconjg returns the double-complex conjugate of its double-complex argument.

cos, dcos, ccos - Fortran cosine intrinsic function

# **SYNOPSIS**

real r1, r2
double precision dp1, dp2
complex cx1, cx2
r2 = cos(r1)
dp2 = dcos(dp1)
dp2 = cos(dp1)
cx2 = ccos(cx1)
cx2 = cos(cx1)

# DESCRIPTION

Cos returns the real cosine of its real argument. Dcos returns the double-precision cosine of its double-precision argument. Ccos returns the complex cosine of its complex argument. The generic form cos may be used with impunity as its returned type is determined by that of its argument.

# SEE ALSO

cosh, dcosh - Fortran hyperbolic cosine intrinsic function

## **SYNOPSIS**

real r1, r2
double precision dp1, dp2
r2 = cosh(r1)
dp2 = dcosh(dp1)
dp2 = cosh(dp1)

# **DESCRIPTION**

Cosh returns the real hyperbolic cosine of its real argument. Dcosh returns the double-precision hyperbolic cosine of its double-precision argument. The generic form cosh may be used to return the hyperbolic cosine in the type of its argument.

# SEE ALSO

sinh(3M).

DIM(3F)

NAME

dim, ddim, idim - positive difference intrinsic functions

**SYNOPSIS** 

integer a1, a2, a3 a3 = idim(a1, a2)

real a1, a2, a3 a3 = dim(a1, a2)

double precision a1, a2, a3 a3 = ddim(a1, a2)

# DESCRIPTION

These functions return:

$$a1-a2$$
 if  $a1 > a2$   
0 if  $a1 <= a2$ 

DPROD(3F)

DPROD(3F)

NAME

dprod - double precision product intrinsic function

SYNOPSIS

real a1, a2

double precision a3

a3 = dprod(a1, a2)

# DESCRIPTION

Dprod returns the double precision product of its real arguments.

exp, dexp, cexp - Fortran exponential intrinsic function

## **SYNOPSIS**

real r1, r2
double precision dp1, dp2
complex cx1, cx2
r2 = exp(r1)
dp2 = dexp(dp1)
dp2 = exp(dp1)
cx2 = cexp(cx1)
cx2 = exp(cx1)

## DESCRIPTION

Exp returns the real exponential function  $e^x$  of its real argument. Dexp returns the double-precision exponential function of its double-precision argument. Cexp returns the complex exponential function of its complex argument. The generic function exp becomes a call to dexp or cexp as required, depending on the type of its argument.

# SEE ALSO

 $\exp(3M)$ .

dex = demplx(dp, dq)
dcx = dcmplx(cx)
i = ichar(ch)
ch = char(i)
```

# DESCRIPTION

These functions perform conversion from one data type to another.

The function int converts to integer form its real, double precision, complex, or double complex argument. If the argument is real or double precision, int returns the integer whose magnitude is the largest integer that does not exceed the magnitude of the argument and whose sign is the same as the sign of the argument (i.e. truncation). For complex types, the above rule is applied to the real part. ifix and idint convert only real and double precision arguments respectively.

The function real converts to real form an integer, double precision, complex, or double complex argument. If the argument is double precision or double complex, as much precision is kept as is possible. If the argument is one of the complex types, the real part is returned. float and sngl convert only integer and double precision arguments respectively.

The function **dble** converts any *integer*, *real*, *complex*, or *double complex* argument to *double precision* form. If the argument is of a complex type, the real part is returned.

The function cmplx converts its integer, real, double precision, or double complex argument(s) to complex form.

The function dcmplx converts to double complex form its integer, real, double precision, or complex argument(s).

Either one or two arguments may be supplied to **cmplx** and **dcmplx**. If there is only one argument, it is taken as the real part of the complex type and an imaginary part of zero is supplied. If two arguments are supplied, the first is taken as the real part and the second as the imaginary part.

The function ichar converts from a character to an integer depending on the character's position in the collating sequence.

The function char returns the character in the ith position in the processor collating sequence where i is the supplied argument.

For a processor capable of representing n characters,

ichar(char(i)) = i for  $0 \le i < n$ , and

char(ichar(ch)) = ch for any representable character ch.

getarg - return Fortran command-line argument

SYNOPSIS

character\*N c integer i call getarg(i, c)

# DESCRIPTION

Getarg returns the i-th command-line argument of the current process. Thus, if a program were invoked via

foo arg1 arg2 arg3

getarg(2, c) would return the string "arg2" in the character variable c.

# SEE ALSO

getopt(3C).

-1-

getenv - return Fortran environment variable

**SYNOPSIS** 

character\*N c

call getenv("VARIABLE\_NAME", c)

# **DESCRIPTION**

Getenv returns the character-string value of the environment variable represented by its first argument into the character variable of its second argument. If no such environment variable exists, all blanks will be returned.

# SEE ALSO

getenv(3C), environ(5).

iarge - return the number of command line arguments

**SYNOPSIS** 

integer i

i = iargc()

# DESCRIPTION

The iargc function returns the number of command line arguments passed to the program. Thus, if a program were invoked via

foo arg1 arg2 arg3

iargc() would return 3.

# SEE ALSO

getarg(3F).

10/84

10/84

index - return location of Fortran substring

**SYNOPSIS** 

character\*N1 ch1 character\*N2 ch2 integer i

i = index(ch1, ch2)

# DESCRIPTION

Index returns the location of substring ch2 in string ch1. The value returned is the position at which substring ch2 starts, or 0 if it is not present in string ch1. If N2 is greater than N1, a zero is returned.

LEN(3F)

NAME

len - return length of Fortran string

SYNOPSIS

character\*N ch integer i

i = len(ch)

# DESCRIPTION

Len returns the length of string ch.

log, alog, clog - Fortran natural logarithm intrinsic function

## **SYNOPSIS**

```
real r1, r2
double precision dp1, dp2
complex cx1, cx2
r2 = alog(r1)
r2 = \log(r1)
dp2 = dlog(dp1)
dp2 = log(dp1)
cx2 = clog(cx1)
cx2 = log(cx1)
```

## DESCRIPTION

Alog returns the real natural logarithm of its real argument. Dlog returns the double-precision natural logarithm of its double-precision argument. Clog returns the complex logarithm of its complex argument. The generic function log becomes a call to alog, dlog, or clog depending on the type of its argument.

## SEE ALSO

exp(3M).

log10, alog10, dlog10 - Fortran common logarithm intrinsic function

# SYNOPSIS

real r1, r2 double precision dp1, dp2 r2 = alog10(r1) r2 = log10(r1) dp2 = dlog10(dp1) dp2 = log10(dp1)

## DESCRIPTION

Alog10 returns the real common logarithm of its real argument. Dlog10 returns the double-precision common logarithm of its double-precision argument. The generic function log10 becomes a call to alog10 or dlog10 depending on the type of its argument.

# SEE ALSO

exp(3M).

max, max0, amax0, max1, amax1, dmax1 - Fortran maximum-value functions

### **SYNOPSIS**

```
integer i, j, k, l
real a, b, c, d
double precision dp1, dp2, dp3
l = max(i, j, k)
c = max(a, b)
dp = max(a, b, c)
k = max0(i, j)
a = amax0(i, j, k)
i = max1(a, b)
d = amax1(a, b, c)
dp3 = dmax1(dp1, dp2)
```

## DESCRIPTION

The maximum-value functions return the largest of their arguments (of which there may be any number). Max is the generic form which can be used for all data types and takes its return type from that of its arguments (which must all be of the same type). Max0 returns the integer form of the maximum value of its integer arguments; amax0, the real form of its integer arguments; max1, the integer form of its real arguments; amax1, the real form of its real arguments; and dmax1, the double-precision form of its double-precision arguments.

#### SEE ALSO

min(3F).

mclock - return Fortran time accounting

**SYNOPSIS** 

integer i

i = mclock()

# DESCRIPTION

Mclock returns time accounting information about the current process and its child processes. The value returned is the sum of the current process's user time and the user and system times of all child processes.

# SEE ALSO

times(2), clock(3C), system(3F).

ior, iand, not, ieor, ishft, ishftc, ibits, btest, ibset, ibclr, mvbits — bit field manipulation intrinsic functions and subroutines from the Fortran Military Standard (MIL-STD-1753).

### **SYNOPSIS**

```
integer i, k, l, m, n, len
logical b

i = ior(m, n)
i = iand(m, n)
i = not(m)
i = ieor(m, n)
i = ishft(m, k)
i = ishftc(m, k, len)
i = ibits(m, k, len)
b = btest(n, k)
i = ibset(n, k)
call mybits(m, k, len, n, l)
```

### DESCRIPTION

ior, iand, not, ieor — return the same results as and, or, not, xor as defined in bool(3F).

ishft,  $ishftc - \mathbf{m}$  specifies the integer to be shifted.  $\mathbf{k}$  specifies the shift count.  $\mathbf{k} > 0$  indicates a left shift.  $\mathbf{k} = 0$  indicates no shift.  $\mathbf{k} < 0$  indicates a right shift. In ishft, zeros are shifted in. In ishftc, the rightmost len bits are shifted circularly  $\mathbf{k}$  bits. If  $\mathbf{k}$  is greater than the machine word-size, ishftc will not shift

Bit fields are numbered from right to left and the rightmost bit position is zero. The length of the len field must be greater than zero.

ibits — extract a subfield of **len** bits from **m** starting with bit position **k** and extending left for **len** bits. The result field is right justified and the remaining bits are set to zero.

btest — The kth bit of argument **n** is tested. The value of the function is .TRUE. if the bit is a and

ibset - the result is the value of **n** with the kth bit set to 1.

ibclr - the result is the value of **n** with the kth bit set to 0.

mvbits - len bits are moved beginning at position k of argument m to position l of argument n.

### SEE ALSO

bool(3F).

min, min0, amin0, min1, amin1, dmin1 - Fortran minimum-value functions

# **SYNOPSIS**

```
integer i, j, k, l
real a, b, c, d
double precision dp1, dp2, dp3
l = min(i, j, k)
c = min(a, b)
dp = min(a, b, c)
k = min0(i, j)
a = amin0(i, j, k)
i = min1(a, b)
d = amin1(a, b, c)
dp3 = dmin1(dp1, dp2)
```

## DESCRIPTION

The minimum-value functions return the minimum of their arguments (of which there may be any number). Min is the generic form which can be used for all data types and takes its return type from that of its arguments (which must all be of the same type). Min0 returns the integer form of the minimum value of its integer arguments; amin0, the real form of its integer arguments; min1, the integer form of its real arguments; amin1, the real form of its real arguments; and dmin1, the double-precision form of its double-precision arguments.

mod, amod, dmod - Fortran remaindering intrinsic functions

# **SYNOPSIS**

```
integer i, j, k
real r1, r2, r3
double precision dp1, dp2, dp3
k = mod(i, j)
r3 = amod(r1, r2)
r3 = mod(r1, r2)
dp3 = dmod(dp1, dp2)
dp3 = mod(dp1, dp2)
```

# DESCRIPTION

Mod returns the integer remainder of its first argument divided by its second argument. Amod and dmod return, respectively, the real and double-precision whole number remainder of the integer division of their two arguments. The generic version mod will return the data type of its arguments.

irand, rand, srand - random number generator

# SYNOPSIS

integer iseed, i, irand double precision x, rand

# call srand(iseed)

i = irand()

x = rand()

## DESCRIPTION

Irand generates successive pseudo-random integers in the range from 0 to 2\*\*15-1. Rand generates pseudo-random numbers distributed in [0, 1.0]. Srand uses its integer argument to re-initialize the seed for successive invocations of irand and rand.

## SEE ALSO

rand(3C).

anint, dnint, nint, idnint - Fortran nearest integer functions

# **SYNOPSIS**

```
integer i
real r1, r2
double precision dp1, dp2
r2 = anint(r1)
i = nint(r1)
dp2 = anint(dp1)
dp2 = dnint(dp1)
i = nint(dp1)
i = idnint(dp1)
```

## DESCRIPTION

Anint returns the nearest whole real number to its real argument (i.e., int(a+0.5) if  $a \ge 0$ , int(a-0.5) otherwise). Dnint does the same for its double-precision argument. Nint returns the nearest integer to its real argument. *Idnint* is the double-precision version. *Anint* is the generic form of anint and dnint, performing the same operation and returning the data type of its argument. Nint is also the generic form of idnint.

sign, isign, dsign - Fortran transfer-of-sign intrinsic function

# **SYNOPSIS**

```
integer i, j, k
real r1, r2, r3
double precision dp1, dp2, dp3
k = isign(i, j)
k = sign(i, j)
r3 = sign(r1, r2)
dp3 = dsign(dp1, dp2)
dp3 = sign(dp1, dp2)
```

### DESCRIPTION

Isign returns the magnitude of its first argument with the sign of its second argument. Sign and dsign are its real and double-precision counterparts, respectively. The generic version is sign and will devolve to the appropriate type depending on its arguments.

signal - specify Fortran action on receipt of a system signal

SYNOPSIS

integer i, intfc external intfc call signal(i, intfc)

# DESCRIPTION

The argument i specifies the signal to be caught. Signal allows a process to specify a function to be invoked upon receipt of a specific signal. The first argument specifies which fault or exception. The second argument specifies the function to be invoked.

NOTE: The interrupt processing function, *intfc*, does not take an argument.

# SEE ALSO

kill(2), signal(2).

sin, dsin, csin - Fortran sine intrinsic function

## **SYNOPSIS**

real r1, r2
double precision dp1, dp2
complex cx1, cx2
r2 = sin(r1)
dp2 = dsin(dp1)
dp2 = sin(dp1)
cx2 = csin(cx1)
cx2 = sin(cx1)

## **DESCRIPTION**

Sin returns the real sine of its real argument. Dsin returns the double-precision sine of its double-precision argument. Csin returns the complex sine of its complex argument. The generic sin function becomes dsin or csin as required by argument type.

# SEE ALSO

sinh, dsinh - Fortran hyperbolic sine intrinsic function

# **SYNOPSIS**

real r1, r2 double precision dp1, dp2 r2 = sinh(r1) dp2 = dsinh(dp1) dp2 = sinh(dp1)

### DESCRIPTION

Sinh returns the real hyperbolic sine of its real argument. Dsinh returns the double-precision hyperbolic sine of its double-precision argument. The generic form sinh may be used to return a double-precision value when given a double-precision argument.

#### SEE ALSO

sinh(3M).

sqrt, dsqrt, csqrt - Fortran square root intrinsic function

# **SYNOPSIS**

real r1, r2 double precision dp1, dp2 complex cx1, cx2 r2 = sqrt(r1)dp2 = dsqrt(dp1)dp2 = sqrt(dp1)cx2 = csqrt(cx1)cx2 = sqrt(cx1)

### **DESCRIPTION**

Sqrt returns the real square root of its real argument. Dsqrt returns the double-precision square root of its double-precision argument. Csqrt returns the complex square root of its complex argument. Sqrt, the generic form, will become dsqrt or csqrt as required by its argument type.

### SEE ALSO

exp(3M).

lge, lgt, lle, llt - string comparison intrinsic functions

# **SYNOPSIS**

character\*N a1, a2 logical l

l = lge(a1, a2) l = lgt(a1, a2) l = lle(a1, a2) l = llt(a1, a2)

# **DESCRIPTION**

These functions return .TRUE. if the inequality holds and .FALSE. otherwise.

10/84 10/84 -1SYSTEM (3F)

NAME

system - issue a shell command from Fortran

SYNOPSIS

character\*N c

call system(c)

# DESCRIPTION

System causes its character argument to be given to sh(1) as input, as if the string had been typed at a terminal. The current process waits until the shell has completed.

# SEE ALSO

exec(2), system(3S).

sh(1) in the 3B2 Computer System User Reference Manual.

### NAME

tan, dtan - Fortran tangent intrinsic function

# **SYNOPSIS**

real r1, r2 double precision dp1, dp2 r2 = tan(r1) dp2 = dtan(dp1) dp2 = tan(dp1)

### DESCRIPTION

Tan returns the real tangent of its real argument. Dtan returns the double-precision tangent of its double-precision argument. The generic tan function becomes dtan as required with a double-precision argument.

# SEE ALSO

trig(3M).

tanh, dtanh - Fortran hyperbolic tangent intrinsic function

### **SYNOPSIS**

real r1, r2 double precision dp1, dp2 r2 = tanh(r1) dp2 = dtanh(dp1) dp2 = tanh(dp1)

# DESCRIPTION

Tanh returns the real hyperbolic tangent of its real argument. Dtanh returns the double-precision hyperbolic tangent of its double-precision argument. The generic form tanh may be used to return a double-precision value given a double-precision argument.

sinh(3M).

INTRO(4)

NAME

intro - introduction to file formats

# DESCRIPTION

This section outlines the formats of various files. The C struct declarations for the file formats are given where applicable. Usually, these structures can be found in the directories /usr/include or /usr/include/sys.

References of the type name(1M) refer to entries found in Section 1 of the  $UNIX\ System\ V\ Administration\ Utilities\ Guide.$ 

#### NAME

a.out - common assembler and link editor output

#### DESCRIPTION

The file name **a.out** is the output file from the assembler as(1) and the link editor ld(1). Both programs will make *a.out* executable if there were no errors in assembling or linking and no unresolved external references.

A common object file consists of a file header, a UNIX system header, a table of section headers, relocation information, (optional) line numbers, a symbol table, and a string table. The order is given below.

File header. UNIX system header. Section 1 header.

Section n header. Section 1 data.

Section n data.
Section 1 relocation.

Section n relocation.
Section 1 line numbers.

...
Section n line numbers.
Symbol table.
String table.

The last three parts of an object file (line numbers, symbol table and string table) may be missing if the program was linked with the -s option of ld(1) or if they were removed by strip(1). Also note that the relocation information will be absent if there were no unresolved external references after linking. The string table exists only if the symbol table contains symbols with names longer than eight characters.

The sizes of each section (contained in the header, discussed below) are in bytes and are even.

When an **a.out** file is loaded into memory for execution, three logical segments are set up: the text segment, the data segment (initialized data followed by uninitialized, the latter actually being initialized to all 0's), and a stack. On the 3B2 computers the text segment starts at location 0x808000000.

The **a.out** file produced by ld(1) by default has a number called the magic number 0413 in the first field of the UNIX system header. The headers (file header, UNIX system header, and section headers) are loaded at the beginning of the text segment and the text immediately follows the headers in the user address space. The first text address will equal the size of the headers, and will vary depending upon the number of section headers in the **a.out** file. In an **a.out** file with three sections (.text, .data, and .bss), the first text address is at 0x808000A8 on the 3B2 computers. The text segment is not writable by the program; if other processes are executing the same **a.out** file, the processes will share a single text segment.

The data segment starts at the next segment boundary (512k on the 3B2 computers) past the last text address. The first data address is determined by the following: If an **a.out** file were split into 8k chunks, one of the chunks would contain both the end of text and the beginning of data. When the core image is created, that chunk will appear twice; once at the end of text and once at the

beginning of data (with some unused space in between). The duplicated chunk of text that appears at the beginning of data is never executed; is is duplicated so that the operating system may bring in pieces of the file in multiples of the page size without having to realign the beginning of the data section to a page boundary. Therefore the first data address is the sum of the next segment boundary past the end of text plus the remainder of the last text address divided by 8k.

On the 3B2 computer the stack begins at location 0xC0020000 and grows toward higher addresses. On all machines the stack is automatically extended as required. The data segment is extended only as requested by the brk(2) system call.

The value of a word in the text or data portions that is not a reference to an undefined external symbol is exactly the value that will appear in memory when the file is executed. If a word in the text involves a reference to an undefined external symbol, the storage class of the symbol-table entry for that word will be marked as an "external symbol", and the section number will be set to 0. When the file is processed by the link editor and the external symbol becomes defined, the value of the symbol will be added to the word in the file.

#### File Header

The format of the filehdr header is

```
struct filehdr

{

unsigned short f_magic; /* magic number */
unsigned short f_nscns; /* number of sections */
long f_timdat; /* time and date stamp */
long f_symptr; /* file ptr to symtab */
long f_nsyms; /* # symtab entries */
unsigned short f_opthdr; /* sizeof(opt hdr) */
unsigned short f_flags; /* flags */
};
```

### UNIX System Header

The format of the UNIX system header is

```
typedef struct aouthdr
                                  /* magic number */
                magic;
       short
                vstamp;
                                  /* version stamp */
       short
                                  /* text size in bytes, padded */
       long
                tsize;
                                  /* initialized data (.data) */
                dsize;
       long
                                  /* uninitialized data (.bss) */
                bsize;
       long
                                  /* entry point */
       long
                entry;
                                  /* base of text used for this file */
       long
                text start;
       long
                data start;
                                  /* base of data used for this file */
} AOUTHDR;
```

#### Section Header

```
The format of the section header is
```

```
struct scnhdr
                       s_name[SYMNMLEN];/* section name */
       char
                                   /* physical address */
       long
                       s paddr;
       long
                       s vaddr;
                                   /* virtual address */
                                   /* section size */
       long
                       s size;
       long
                       s scnptr;
                                  /* file ptr to raw data */
                       s relptr;
                                   /* file ptr to relocation */
       long
                       s Innoptr; /* file ptr to line numbers */
       long
       unsigned short s nreloc;
                                  /* # reloc entries */
                                   /* # line number entries */
       unsigned short s nlnno;
                                   /* flags */
                       s flags;
};
```

### Relocation

Object files have one relocation entry for each relocatable reference in the text or data. If relocation information is present, it will be in the following format:

```
struct reloc {

long r_vaddr; /* (virtual) address of reference */
long r_symndx; /* index into symbol table */
short r_type; /* relocation type */
};
```

The start of the relocation information is  $s_relptr$  from the section header. If there is no relocation information,  $s_relptr$  is 0.

# Symbol Table

lows.

#define n name

#define n zeroes

#define n\_offset

The format of each symbol in the symbol table is #define SYMNMLEN 8 #define FILNMLEN 14 #define SYMESZ /\* the size of a SYMENT \*/ 18 struct syment union /\* all ways to get a symbol name \*/ char \_n\_name[SYMNMLEN]; /\* name of symbol \*/ struct n zeroes; /\* == 0L if in string table \*/ long long n offset; /\* location in string table \*/ } \_n\_n; char \*\_n\_nptr[2]; /\* allows overlaying \*/ } \_n; unsigned long n\_value; /\* value of symbol \*/ short n scnum; /\* section number \*/ unsigned short /\* type and derived type \*/ n\_type; /\* storage class \*/ char n\_sclass; /\* number of aux entries \*/ char n numaux; **}**;

#define n\_nptr \_\_n.\_n\_nptr[1]
Some symbols require more information than a single entry; they are followed by auxiliary entries that are the same size as a symbol entry. The format fol-

\_n.\_n\_name

\_n.\_n\_n.\_n\_zeroes

\_n.\_n\_n.\_n\_offset

```
union auxent {
      struct {
            long
                    x_tagndx;
            union {
                    struct {
                            unsigned short x lnno;
                            unsigned short x size;
                    } x lnsz;
                    long
                            x fsize;
            } x misc;
            union {
                    struct {
                            long
                                    x lnnoptr;
                            long
                                    x endndx;
                    x fcn;
                    struct {
                            unsigned short x dimen[DIMNUM];
                    } x ary;
            } x fcnary;
            unsigned short x_tvndx;
      } x_sym;
      struct {
            char
                    x fname[FILNMLEN];
      } x file;
      struct {
                       x scnlen;
            unsigned short x nreloc;
            unsigned short x nlinno;
      } x scn;
      struct {
                            x tvfill;
            unsigned short x tvlen;
            unsigned short x tvran[2];
      } x tv;
}:
```

Indexes of symbol table entries begin at zero. The start of the symbol table is  $f\_symptr$  (from the file header) bytes from the beginning of the file. If the symbol table is stripped,  $f\_symptr$  is 0. The string table (if one exists) begins at  $f\_symptr + (f\_nsyms * SYMESZ)$  bytes from the beginning of the file.

AR (4)

#### NAME

ar - common archive file format

#### DESCRIPTION

The archive command ar(1) is used to combine several files into one. Archives are used mainly as libraries to be searched by the link editor ld(1).

Each archive begins with the archive magic string.

```
#define ARMAG "!<arch>\n" /* magic string */
#define SARMAG 8 /* length of magic string */
```

Each archive which contains common object files (see a.out(4)) includes an archive symbol table. This symbol table is used by the link editor ld(1) to determine which archive members must be loaded during the link edit process. The archive symbol table (if it exists) is always the first file in the archive (but is never listed) and is automatically created and/or updated by ar.

Following the archive magic string are the archive file members. Each file member is preceded by a file member header which is of the following format:

```
"'\n"
#define ARFMAG
                                  /* header trailer string */
struct ar hdr
                                  /* file member header */
                                  /* '/' terminated file member name */
          ar name[16];
   char
   char
          ar date[12];
                                  /* file member date */
                                  /* file member user identification */
   char
          ar uid[6];
                                  /* file member group identification */
   char
          ar gid[6];
                                  /* file member mode (octal) */
   char
          ar mode[8];
                                  /* file member size */
   char
          ar size[10];
                                  /* header trailer string */
   char
          ar fmag[2];
}:
```

All information in the file member headers is in printable ASCII. The numeric information contained in the headers is stored as decimal numbers (except for  $ar\_mode$  which is in octal). Thus, if the archive contains printable files, the archive itself is printable.

The  $ar_name$  field is blank-padded and slash (/) terminated. The  $ar_name$  field is the modification date of the file at the time of its insertion into the archive. Common format archives can be moved from system to system as long as the portable archive command ar(1) is used. Conversion tools such as arcv(1) and convert(1) exist to aid in the transportation of non-common format archives to this format.

Each archive file member begins on an even byte boundary; a newline is inserted between files if necessary. Nevertheless the size given reflects the actual size of the file exclusive of padding.

Notice there is no provision for empty areas in an archive file.

If the archive symbol table exists, the first file in the archive has a zero length name (i.e., ar name[0] == '/'). The contents of this file are as follows:

- The number of symbols. Length: 4 bytes.
- The array of offsets into the archive file. Length: 4 bytes \* "the number of symbols".

AR(4) AR(4)

• The name string table. Length:  $ar\_size - (4 \text{ bytes * ("the number of symbols"} + 1)).$ 

The number of symbols and the array of offsets are managed with *sgetl* and *sputl*. The string table contains exactly as many null terminated strings as there are elements in the offsets array. Each offset from the array is associated with the corresponding name from the string table (in order). The names in the string table are all the defined global symbols found in the common object files in the archive. Each offset is the location of the archive header for the associated symbol.

### SEE ALSO

sputl(3X), a.out(4).

ar(1), ld(1), strip(1) in the 3B2 Computer System Software Generation System Utilities.

# WARNINGS

Strip (1) will remove all archive symbol entries from the header. The archive symbol entries must be restored via the ts option of the ar(1) command before the archive can be used with the link editor ld(1).

CHECKLIST (4) CHECKLIST (4)

### NAME

checklist - list of file systems processed by fsck

### **DESCRIPTION**

Checklist resides in directory /etc and contains a list of, at most, 15 special file names. Each special file name is contained on a separate line and corresponds to a file system. Each file system will then be automatically processed by the fsck(1M) command.

# SEE ALSO

fsck(1M) in the 3B2 Computer System Administration Utilities Guide.

CORE(4) CORE(4)

#### NAME

core - format of core image file

#### DESCRIPTION

The UNIX system writes out a core image of a terminated process when any of various errors occur. See *signal*(2) for the list of reasons; the most common are memory violations, illegal instructions, bus errors, and user-generated quit signals. The core image is called **core** and is written in the process's working directory (provided it can be; normal access controls apply). A process with an effective user ID different from the real user ID will not produce a core image.

The first section of the core image is a copy of the system's per-user data for the process, including the registers as they were at the time of the fault. The size of this section depends on the parameter usize, which is defined in /usr/include/sys/param.h. The remainder represents the actual contents of the user's core area when the core image was written. If the text segment is read-only and shared, or separated from data space, it is not dumped.

The format of the information in the first section is described by the *user* structure of the system, defined in /usr/include/sys/user.h. The important stuff not detailed therein is the locations of the registers, which are outlined in /usr/include/sys/reg.h.

cpio - format of cpio archive

### DESCRIPTION

The header structure, when the -c option of cpio(1) is not used, is:

```
struct {
```

} Hdr:

```
short
         h magic,
         h dev;
ushort
         h ino,
         h mode,
         h uid,
         h gid;
         h_nlink,
short
         h rdev,
         h mtime[2],
         h namesize,
         h filesize[2];
char
         h name[h namesize rounded to word];
```

When the -c option is used, the *header* information is described by:

```
sscanf(Chdr,"%60%60%60%60%60%60%60%60%1110%60%1110%s",
&Hdr.h_magic, &Hdr.h_dev, &Hdr.h_ino, &Hdr.h_mode,
&Hdr.h_uid, &Hdr.h_gid, &Hdr.h_nlink, &Hdr.h_rdev,
&Longtime, &Hdr.h namesize,&Longfile,Hdr.h name);
```

Longtime and Longfile are equivalent to  $Hdr.h\_mtime$  and  $Hdr.h\_filesize$ , respectively. The contents of each file are recorded in an element of the array of varying length structures, archive, together with other items describing the file. Every instance of  $h\_magic$  contains the constant 070707 (octal). The items  $h\_dev$  through  $h\_mtime$  have meanings explained in stat(2). The length of the null-terminated path name  $h\_name$ , including the null byte, is given by  $h\_namesize$ .

The last record of the *archive* always contains the name TRAILER!!!. Special files, directories, and the trailer are recorded with *h filesize* equal to zero.

DIR (4) DIR (4)

NAME

dir - format of directories

### **SYNOPSIS**

#include <sys/dir.h>

### DESCRIPTION

A directory behaves exactly like an ordinary file, save that no user may write into a directory. The fact that a file is a directory is indicated by a bit in the flag word of its i-node entry (see fs(4)). The structure of a directory entry as given in the include file is:

```
#ifndef DIRSIZ
#define DIRSIZ
                    14
#endif
struct
        direct
        ino_t d_ino;
        char d_name[DIRSIZ];
};
```

By convention, the first two entries in each directory are for . and ... The first is an entry for the directory itself. The second is for the parent directory. The meaning of .. is modified for the root directory of the master file system; there is no parent, so .. has the same meaning as ..

fs(4).

FILEHDR (4) FILEHDR (4)

```
NAME
```

filehdr - file header for common object files

#### SYNOPSIS

```
#include <filehdr.h>
```

#### DESCRIPTION

Every common object file begins with a 20-byte header. The following C struct declaration is used:

```
struct filehdr {

unsigned short f_magic; /* magic number */
unsigned short f_nscns; /* number of sections */
long f_timdat; /* time & date stamp */
long f_symptr; /* file ptr to symtab */
long f_nsyms; /* # symtab entries */
unsigned short f_opthdr; /* sizeof(opt hdr) */
unsigned short f_flags; /* flags */
};
```

 $F\_symptr$  is the byte offset into the file at which the symbol table can be found. Its value can be used as the offset in fseek (3S) to position an I/O stream to the symbol table. The UNIX system optional header is 28-bytes. The valid magic numbers are given below:

```
#define N3BMAGIC 0550 /* 3B20 computer */
#define NTVMAGIC 0551 /* 3B20 computer */
#define VAXWRMAGIC 0570 /* VAX writable text segments */
#define VAXROMAGIC 0575 /* VAX readonly sharable text segments */
#define FBOMAGIC 0570 /* 3B5 and 3B2 computers */
```

The value in  $f_{timdat}$  is obtained from the time(2) system call. Flag bits currently defined are:

```
#define F RELFLG
                    0000001
                               /* relocation entries stripped */
#define F_EXEC
                    0000002

FS(4) FS(4)

#### NAME

file system - format of system volume

#### SYNOPSIS

```
#include <sys/filsys.h>
#include <sys/types.h>
#include <sys/param.h>
```

#### DESCRIPTION

Every file system storage volume has a common format for certain vital information. Every such volume is divided into a certain number of 512-byte long sectors. Sector 0 is unused and is available to contain a bootstrap program or other information.

Sector 1 is the super-block. The format of a super-block is:

```
* Structure of the super-block
 */
struct
         filsys
                                             /* size in blocks of i-list */
         ushort
                      s isize;
         daddr t
                      s fsize;
                                             /* size in blocks of entire volume */
         short
                      s nfree;
                                             /* number of addresses in s free */
         daddr t
                      s free[NICFREE];
                                             /* free block list */
                                             /* number of i-nodes in s_inode */
         short
                      s ninode;
         ino t
                      s_inode[NICINOD];
                                             /* free i-node list */
         char
                      s flock;
                                             /* lock during free list manipulation */
         char
                      s_ilock;
                                             /* lock during i-list manipulation */
         char
                      s_fmod;
                                             /* super block modified flag */
                                             /* mounted read-only flag */
         char
                      s ronly;
         time t
                      s time;
                                             /* last super block update */
         short
                      s dinfo[4];
                                             /* device information */
         daddr t
                      s tfree;
                                             /* total free blocks*/
         ino t
                      s tinode;
                                             /* total free i-nodes */
                      s fname[6];
                                             /* file system name */
         char
         char
                      s fpack[6];
                                             /* file system pack name */
                      s_fill[12];
                                             /* ADJUST to make sizeof filsys
         long
                                             be 512 */
                                             /* file system state */
         long
                      s state;
                                             /* magic number to denote new
         long
                      s_magic;
                                             file system */
         long
                                             /* type of new file system */
                      s type;
};
#define FsMAGIC
                      0xfd187e20
                                             /* s magic number */
#define Fs1b
                                             /* 512-byte block */
                      1
#define Fs2b
                                             /* 1024-byte block */
#define FsOKAY
                      0x7c269d38
                                             /* s_state: clean */
#define FsACTIVE
                      0x5e72d81a
                                             /* s state: active */
#define FsBAD
                      0xcb096f43
                                             /* s state: bad root */
```

 $S\_type$  indicates the file system type. Currently, two types of file systems are supported: the original 512-byte oriented and the new improved 1024-byte oriented.  $S\_magic$  is used to distinguish the original 512-byte oriented file systems from the newer file systems. If this field is not equal to the magic number, FsMAGIC, the type is assumed to be Fs1b, otherwise the  $s\_type$  field

is used. In the following description, a block is then determined by the type. For the original 512-byte oriented file system, a block is 512-bytes. For the 1024-byte oriented file system, a block is 1024-bytes or two sectors. The operating system takes care of all conversions from logical block numbers to physical sector numbers.

S\_state indicates the state of the file system. A cleanly unmounted, not damaged file system is indicated by the Fsokay state. After a file system has been mounted for update, the state changes to Fsactive. A special case is used for the root file system. If the root file system appears damaged at boot time, it is mounted but marked Fsbad. Lastly, after a file system has been unmounted, the state reverts to Fsokay.

 $S\_isize$  is the address of the first data block after the i-list; the i-list starts just after the super-block, namely in block 2; thus the i-list is  $s\_isize-2$  blocks long.  $S\_fsize$  is the first block not potentially available for allocation to a file. These numbers are used by the system to check for bad block numbers; if an "impossible" block number is allocated from the free list or is freed, a diagnostic is written on the on-line console. Moreover, the free array is cleared, so as to prevent further allocation from a presumably corrupted free list.

The free list for each volume is maintained as follows. The s\_free array contains, in s\_free[1], ..., s\_free[s\_nfree-1], up to 49 numbers of free blocks. S\_free[0] is the block number of the head of a chain of blocks constituting the free list. The first long in each free-chain block is the number (up to 50) of free-block numbers listed in the next 50 longs of this chain member. The first of these 50 blocks is the link to the next member of the chain. To allocate a block: decrement s\_nfree, and the new block is s\_free[s\_nfree]. If the new block number is 0, there are no blocks left, so give an error. If s\_nfree became 0, read in the block named by the new block number, replace s\_nfree by its first word, and copy the block numbers in the next 50 longs into the s\_free array. To free a block, check if s\_nfree is 50; if so, copy s\_nfree and the s\_free array into it, write it out, and set s\_nfree to 0. In any event set s\_free[s\_nfree] to the freed block's number and increment s\_nfree.

S tfree is the total free blocks available in the file system.

S\_ninode is the number of free i-numbers in the s\_inode array. To allocate an i-node: if s\_ninode is greater than 0, decrement it and return s\_inode[s\_ninode]. If it was 0, read the i-list and place the numbers of all free i-nodes (up to 100) into the s\_inode array, then try again. To free an i-node, provided s\_ninode is less than 100, place its number into s\_inode[s\_ninode] and increment s\_ninode. If s\_ninode is already 100, do not bother to enter the freed i-node into any table. This list of i-nodes is only to speed up the allocation process; the information as to whether the i-node is really free or not is maintained in the i-node itself.

S\_tinode is the total free i-nodes available in the file system.

 $S\_flock$  and  $s\_ilock$  are flags maintained in the core copy of the file system while it is mounted and their values on disk are immaterial. The value of  $s\_fmod$  on disk is likewise immaterial; it is used as a flag to indicate that the super-block has changed and should be copied to the disk during the next periodic update of file system information.

S ronly is a read-only flag to indicate write-protection.

 $S\_time$  is the last time the super-block of the file system was changed, and is the number of seconds that have elapsed since 00:00 Jan. 1, 1970 (GMT). During a reboot, the  $s\_time$  of the super-block for the root file system is used to set the system's idea of the time.

FS (4)

S\_fname is the name of the file system and s\_fpack is the name of the pack.

I-numbers begin at 1, and the storage for i-nodes begins in block 2. Also, i-nodes are 64 bytes long. I-node 1 is reserved for future use. I-node 2 is reserved for the root directory of the file system, but no other i-number has a built-in meaning. Each i-node represents one file. For the format of an i-node and its flags, see *inode* (4).

FSPEC(4) FSPEC(4)

NAME

fspec - format specification in text files

#### DESCRIPTION

It is sometimes convenient to maintain text files on the UNIX system with nonstandard tabs, (i.e., tabs which are not set at every eighth column). Such files must generally be converted to a standard format, frequently by replacing all tabs with the appropriate number of spaces, before they can be processed by UNIX system commands. A format specification occurring in the first line of a text file specifies how tabs are to be expanded in the remainder of the file.

A format specification consists of a sequence of parameters separated by blanks and surrounded by the brackets <: and :>. Each parameter consists of a keyletter, possibly followed immediately by a value. The following parameters are recognized:

ttabs The t parameter specifies the tab settings for the file. The value of tabs must be one of the following:

- 1. a list of column numbers separated by commas, indicating tabs set at the specified columns;
- a followed immediately by an integer n, indicating tabs at intervals of n columns;
- 3. a followed by the name of a "canned" tab specification.

Standard tabs are specified by t-8, or equivalently, t1,9,17,25, etc. The canned tabs which are recognized are defined by the tabs(1) command.

ssize The s parameter specifies a maximum line size. The value of size must be an integer. Size checking is performed after tabs have been expanded, but before the margin is prepended.

mmargin The m parameter specifies a number of spaces to be prepended to each line. The value of margin must be an integer.

- d The d parameter takes no value. Its presence indicates that the line containing the format specification is to be deleted from the converted file.
- e The e parameter takes no value. Its presence indicates that the current format is to prevail only until another format specification is encountered in the file.

Default values, which are assumed for parameters not supplied, are t-8 and m0. If the s parameter is not specified, no size checking is performed. If the first line of a file does not contain a format specification, the above defaults are assumed for the entire file. The following is an example of a line containing a format specification:

\* <:t5,10,15 s72:> \*

If a format specification can be disguised as a comment, it is not necessary to code the  $\mathbf{d}$  parameter.

Several UNIX system commands correctly interpret the format specification for a file. Among them is *gath* (see *send* (1C)) which may be used to convert files to a standard format acceptable to other UNIX system commands.

GETTYDEFS (4) GETTYDEFS (4)

NAME

gettydefs - speed and terminal settings used by getty

#### DESCRIPTION

The /etc/gettydefs file contains information used by getty(1M) to set up the speed and terminal settings for a line. It supplies information on what the login prompt should look like. It also supplies the speed to try next if the user indicates the current speed is not correct by typing a <br/>
break character.

Each entry in /etc/gettydefs has the following format:

label# initial-flags # final-flags # login-prompt #next-label

Each entry is followed by a blank line. The various fields can contain quoted characters of the form b, n, c, etc., as well as nnn, where nnn is the octal value of the desired character. The various fields are:

label

This is the string against which *getty* tries to match its second argument. It is often the speed, such as 1200, at which the terminal is supposed to run, but it need not be (see below).

initial-flags

These flags are the initial *ioctl*(2) settings to which the terminal is to be set if a terminal type is not specified to *getty*. The flags that *getty* understands are the same as the ones listed in /usr/include/sys/termio.h (see *termio*(7)). Normally only the speed flag is required in the *initial-flags*. *Getty* automatically sets the terminal to raw input mode and takes care of most of the other flags. The *initial-flag* settings remain in effect until *getty* executes *login*(1).

final-flags

These flags take the same values as the *initial-flags* and are set just prior to *getty* executes *login*. The speed flag is again required. The composite flag SANE takes care of most of the other flags that need to be set so that the processor and terminal are communicating in a rational fashion. The other two commonly specified *final-flags* are TAB3, so that tabs are sent to the terminal as spaces, and HUPCL, so that the line is hung up on the final close.

login-prompt

This entire field is printed as the *login-prompt*. Unlike the above fields where white space is ignored (a space, tab or newline), they are included in the *login-prompt* field.

next-label

If this entry does not specify the desired speed, indicated by the user typing a <br/>break> character, then getty will search for the entry with next-label as its label field and set up the terminal for those settings. Usually, a series of speeds are linked together in this fashion, into a closed set; For instance, 2400 linked to 1200, which in turn is linked to 300, which finally is linked to 2400.

If getty is called without a second argument, then the first entry of /etc/gettydefs is used, thus making the first entry of /etc/gettydefs the default entry. It is also used if getty can not find the specified label. If /etc/gettydefs itself is missing, there is one entry built into the command which will bring up a terminal at 300 baud.

It is strongly recommended that after making or modifying /etc/gettydefs, it be run through getty with the check option to be sure there are no errors.

GPS (4) GPS (4)

NAME

gps - graphical primitive string, format of graphical files

#### DESCRIPTION

GPS is a format used to store graphical data. Several routines have been developed to edit and display GPS files on various devices. Also, higher level graphics programs such as plot (in stat(1G)) and vtoc (in toc(1G)) produce GPS format output files.

A GPS is composed of five types of graphical data or primitives.

#### **GPS PRIMITIVES**

lines

The *lines* primitive has a variable number of points from which zero or more connected line segments are produced. The first point given produces a *move* to that location. (A *move* is a relocation of the graphic cursor without drawing.) Successive points produce line segments from the previous point. Parameters are available to set *color*, *weight*, and *style* (see below).

arc

The arc primitive has a variable number of points to which a curve is fit. The first point produces a move to that point. If only two points are included, a line connecting the points will result; if three points a circular arc through the points is drawn; and if more than three, lines connect the points. (In the future, a spline will be fit to the points if they number greater than three.) Parameters are available to set color, weight, and style.

text

The *text* primitive draws characters. It requires a single point which locates the center of the first character to be drawn. Parameters are *color*, *font*, *textsize*, and *textangle*.

hardware

The *hardware* primitive draws hardware characters or gives control commands to a hardware device. A single point locates the beginning location of the *hardware* string.

comment

A comment is an integer string that is included in a GPS file but causes nothing to be displayed. All GPS files begin with a comment of zero length.

#### **GPS PARAMETERS**

color

Color is an integer value set for arc, lines, and text primitives.

weight

Weight is an integer value set for arc and lines primitives to indicate line thickness. The value 0 is narrow weight, 1 is bold, and 2 is medium weight.

style

Style is an integer value set for *lines* and *arc* primitives to give one of the five different line styles that can be drawn on TEKTRONIX 4010 series storage tubes. They are:

- 0 solid
- 1 dotted
- 2 dot dashed
- 3 dashed
- 4 long dashed

font

An integer value set for *text* primitives to designate the text font to be used in drawing a character string. (Currently *font* is expressed as a four-bit *weight* value followed by a four-bit *style* value.)

textsize

Textsize is an integer value used in text primitives to express the size of the characters to be drawn. Textsize represents the height of characters in absolute universe-units and is stored at one-fifth this value in the size-orientation (so) word (see below).

textangle is a signed integer value used in text primitives to express rotation of the character string around the beginning point.

Textangle is expressed in degrees from the positive x-axis and can be a positive or negative value. It is stored in the size-orientation (so) word as a value 256/360 of it's absolute value.

#### ORGANIZATION

GPS primitives are organized internally as follows:

lines cw points sw
arc cw points sw
text cw point sw so [string]
hardware cw point [string]

comment cw [string]

cw Cw is the control word and begins all primitives. It consists of four

bits that contain a primitive-type code and twelve bits that contain the word-count for that primitive.

point(s) Point(s) is one or more pairs of integer coordinates. Text and hardware primitives only require a single point. Point(s) are values within a Cartesian plane or universe having 64K (-32K to +32K) points on each axis.

Sw is the style-word and is used in *lines*, arc, and text primitives. For all three, eight bits contain color information. In arc and lines eight bits are divided as four bits weight and four bits style. In the text primitive eight bits of sw contain the font.

So is the size-orientation word used in *text* primitives. Eight bits contain text size and eight bits contain text rotation.

String is a null-terminated character string. If the string does not end on a word boundary, an additional null is added to the GPS file to insure word-boundary alignment.

GROUP(4) GROUP(4)

NAME

group - group file

# DESCRIPTION

Group contains for each group the following information:

group name encrypted password numerical group ID comma-separated list of all users allowed in the group

This is an ASCII file. The fields are separated by colons; each group is separated from the next by a new-line. If the password field is null, no password is demanded.

This file resides in directory /etc. Because of the encrypted passwords, it can and does have general read permission and can be used, for example, to map numerical group ID's to names.

NAME

inittab - script for the init process

#### DESCRIPTION

The *inittab* file supplies the script to *init*'s role as a general process dispatcher. The process that constitutes the majority of *init*'s process dispatching activities is the line process /etc/getty that initiates individual terminal lines. Other processes typically dispatched by *init* are daemons and the shell.

The *inittab* file is composed of entries that are position dependent and have the following format:

id:rstate:action:process

Each entry is delimited by a newline, however, a backslash (\) preceding a newline indicates a continuation of the entry. Up to 512 characters per entry are permitted. Comments may be inserted in the *process* field using the sh(1) convention for comments. Comments for lines that spawn gettys are displayed by the who(1) command. It is expected that they will contain some information about the line such as the location. There are no limits (other than maximum entry size) imposed on the number of entries within the *inittab* file. The entry fields are:

id This is one or two characters used to uniquely identify an entry.

rstate

This defines the run-level in which this entry is to be processed. Run-levels effectively correspond to a configuration of processes in the system. That is, each process spawned by init is assigned a run-level or run-levels in which it is allowed to exist. The run-levels are represented by a number ranging from 0 through 6. As an example, if the system is in run-level 1, only those entries having a 1 in the rstate field will be processed. When init is requested to change runlevels, all processes which do not have an entry in the rstate field for the target run-level will be sent the warning signal (SIGTERM) and allowed a 20-second grace period before being forcibly terminated by a kill signal (SIGKILL). The rstate field can define multiple runlevels for a process by selecting more than one run-level in any combination from 0-6. If no run-level is specified, then the process is assumed to be valid at all run-levels 0-6. There are three other values, a, b and c, which can appear in the rstate field, even though they are not true run-levels. Entries which have these characters in the rstate field are processed only when the telinit (see init (1M)) process requests them to be run (regardless of the current run-level of the system). They differ from run-levels in that init can never enter run-level a, b or c. Also, a request for the execution of any of these processes does not change the current run-level. Furthermore, a process started by an a, b or c command is not killed when init changes levels. They are only killed if their line in /etc/inittab is marked off in the action field, their line is deleted entirely from /etc/inittab, or init goes into the SINGLE USER state.

action

Key words in this field tell *init* how to treat the process specified in the *process* field. The actions recognized by *init* are as follows:

respawn

If the process does not exist then start the process, do not wait for its termination (continue scanning the *inittab* file), and when it dies restart the process. If the process currently exists then do nothing and continue scanning the *inittab* file.

10/84

INITTAB(4) INITTAB(4)

wait Upon *init*'s entering the *run-level* that matches the entry's *rstate*, start the process and wait for its termination. All subsequent reads of the *inittab* file while *init* is in the same *run-level* will cause *init* to ignore this entry.

Once Upon init's entering a run-level that matches the entry's rstate, start the process, do not wait for its termination. When it dies, do not restart the process. If upon entering a new run-level, where the process is still running from a previous run-level change, the program will not be restarted.

The entry is to be processed only at *init*'s boot-time read of the *inittab* file. *Init* is to start the process, not wait for its termination; and when it dies, not restart the process. In order for this instruction to be meaningful, the *rstate* should be the default or it must match *init*'s *run-level* at boot time. This action is useful for an initialization function following a hardware reboot of the system.

bootwait The entry is to be processed only at *init*'s boot-time read of the *inittab* file. *Init* is to start the process, wait for its termination and, when it dies, not restart the process.

**powerfail** Execute the process associated with this entry only when *init* receives a power fail signal (SIGPWR see signal (2)).

powerwait Execute the process associated with this entry only when init receives a power fail signal (SIGPWR) and wait until it terminates before continuing any processing of inittab.

If the process associated with this entry is currently running, send the warning signal (SIGTERM) and wait 20 seconds before forcibly terminating the process via the kill signal (SIGKILL). If the process is nonexistent, ignore the entry.

ondemand This instruction is really a synonym for the respawn action. It is functionally identical to respawn but is given a different keyword in order to divorce its association with run-levels. This is used only with the a, b or c values described in the rstate field.

initdefault An entry with this action is only scanned when init initially invoked. Init uses this entry, if it exists, to determine which run-level to enter initially. It does this by taking the highest run-level specified in the rstate field and using that as its initial state. If the rstate field is empty, this is interpreted as 0123456 and so init will enter run-level 6. Also, the initdefault entry cannot specify that init start in the SINGLE USER state. Additionally, if init does not find an initdefault entry in /etc/inittab, then it will request an initial run-level from the user at reboot time.

10/84

10/84 - 2 -

off

INITTAB(4) INITTAB(4)

sysinit

Entries of this type are executed before *init* tries to access the console. It is expected that this entry will be only used to initialize devices on which *init* might try to ask the *run-level* question. These entries are executed and waited for before continuing.

process This is a sh command to be executed. The entire process field is prefixed with exec and passed to a forked sh as sh -c 'exec command'. For this reason, any legal sh syntax can appear in the process field. Comments can be inserted with the; #comment syntax.

INODE (4) INODE(4)

```
NAME
        inode - format of an i-node
SYNOPSIS
        #include <sys/types.h>
        #include <sys/ino.h>
DESCRIPTION
        An i-node for a plain file or directory in a file system has the following struc-
        ture defined by <sys/ino.h>.
                /* Inode structure as it appears on a disk block. */
                struct dinode
                       ushort di_mode;
                                           /* mode and type of file */
                                           /* number of links to file */
                       short di nlink;
                       ushort di uid;
                                           /* owner's user id */
                                           /* owner's group id */
                       ushort di_gid;
                                           /* number of bytes in file */
                       off_t
                              di size;
                              di addr[40]; /* disk block addresses */
                       char
                                           /* time last accessed */
                       time t di atime;
                                           /* time last modified */
                       time_t di_mtime;
                       time t di ctime;
                                           /* time of last file status change */
                };
                 * the 40 address bytes:
                      39 used; 13 addresses
                      of 3 bytes each.

LDFCN(4) LDFCN(4)

NAME

ldfcn - common object file access routines

#### **SYNOPSIS**

#include <stdio.h> #include <filehdr.h> #include <ldfcn.h>

#### DESCRIPTION

The common object file access routines are a collection of functions for reading an object file that is in computer (common) object file form. Although the calling program must know the detailed structure of the parts of the object file that it processes, the routines effectively insulate the calling program from knowledge of the overall structure of the object file.

The interface between the calling program and the object file access routines is based on the defined type LDFILE, defined as struct ldfile, declared in the header file ldfcn.h. The primary purpose of this structure is to provide uniform access to both simple object files and to object files that are members of an archive file.

The function *ldopen*(3X) allocates and initializes the LDFILE structure and returns a pointer to the structure to the calling program. The fields of the LDFILE structure may be accessed individually through macros defined in ldfcn.h and contain the following information:

LDFILE \*ldptr;

TYPE(ldptr) The file magic number used to distinguish between archive

members and simple object files.

IOPTR (ldptr) The file pointer returned by fopen and used by the standard

input/output functions.

OFFSET(ldptr) The file address of the beginning of the object file; the offset is

non-zero if the object file is a member of an archive file.

HEADER (ldptr) The file header structure of the object file.

The object file access functions themselves may be divided into four categories:

(1) functions that open or close an object file

ldopen(3X) and ldopen(3X)
open a common object file
ldclose(3X) and ldclose(3X)
close a common object file

(2) functions that read header or symbol table information

ldahread (3X)

read the archive header of a member of an archive file *ldfhread* (3X)

read the file header of a common object file

ldshread(3X) and ldshread(3X)

read a section header of a common object file *ldtbread* (3X)

read a symbol table entry of a common object file ldgetname (3X)

retrieve a symbol name from a symbol table entry or from the string table

(3) functions that position an object file at (seek to) the start of the section, relocation, or line number information for a particular section.

LDFCN(4) LDFCN(4)

ldohseek (3X)

seek to the optional file header of a common object file

ldsseek (3X) and ldsseek (3X)

seek to a section of a common object file

ldrseek (3X) and ldrseek (3X)

seek to the relocation information for a section of a common object file

Idlseek (3X) and Idlseek (3X)

seek to the line number information for a section of a common object file

ldtbseek (3X)

seek to the symbol table of a common object file

(4) the function *ldtbindex* (3X) which returns the index of a particular common object file symbol table entry.

These functions are described in detail on their respective manual pages.

All the functions except ldopen(3X), ldgetname(3X), ldopen(3X), and ldtbindex(3X) return either SUCCESS or FAILURE, both constants defined in ldfen.h. Ldopen(3X) and ldopen(3X) both return pointers to an LDFILE structure.

Additional access to an object file is provided through a set of macros defined in **ldfcn.h**. These macros parallel the standard input/output file reading and manipulating functions, translating a reference of the **LDFILE** structure into a reference to its file descriptor field.

The following macros are provided:

GETC(ldptr)
FGETC(ldptr)
GETW(ldptr)
UNGETC(c, ldptr)
FGETS(s, n, ldptr)
FREAD((char \*) ptr, sizeof (\*ptr), nitems, ldptr)
FSEEK(ldptr, offset, ptrname)
FTELL(ldptr)
REWIND(ldptr)
FEOF(ldptr)
FERROR(ldptr)
FILENO(ldptr)
SETBUF(ldptr, buf)
STROFFSET(ldptr)

The STROFFSET macro calculates the address of the string table in a UNIX system release 5.0 object file. See the manual entries for the corresponding standard input/output library functions for details on the use of the rest of the macros

The program must be loaded with the object file access routine library libld.a.

# SEE ALSO

fseek(3S), ldahread(3X), ldclose(3X), ldgetname(3X), ldfhread(3X), ldlread(3X), ldlseek(3X), ldohseek(3X), ldopen(3X), ldrseek(3X), ldshread(3X), ldtbread(3X), ldtbread(3X), ldtbread(3X), intro(5).

#### WARNING

The macro FSEEK defined in the header file **ldfcn.h** translates into a call to the standard input/output function *fseek* (3S). FSEEK should not be used to seek from the end of an archive file since the end of an archive file may not be the same as the end of one of its object file members!

LINENUM (4) LINENUM (4)

### NAME

linenum - line number entries in a common object file

#### **SYNOPSIS**

#include linenum.h>

#### DESCRIPTION

Compilers based on pcc generate an entry in the object file for each C source line on which a breakpoint is possible (when invoked with the -g option; see cc(1)). Users can then reference line numbers when using the appropriate software test system (see sdb(1)). The structure of these line number entries appears below.

```
struct lineno
{
    union
    {
        long l_symndx;
        long l_paddr;
    }
        l_addr;
    unsigned short l_lnno;
};
```

Numbering starts with one for each function. The initial line number entry for a function has  $l\_lnno$  equal to zero, and the symbol table index of the function's entry is in  $l\_symndx$ . Otherwise,  $l\_lnno$  is non-zero, and  $l\_paddr$  is the physical address of the code for the referenced line. Thus the overall structure is the following:

```
l_addr l_lnno

function symtab index 0
physical address line
physical address line
...

function symtab index 0
physical address line
physical address line
```

MASTER (4) MASTER (4)

#### NAME

master - master configuration database

### DESCRIPTION

The *master* configuration database is a collection of files. Each file contains configuration information for a device or module that may be included in the system. A file is named with the module name to which it applies. This collection of files is maintained in a directory called /etc/master.d. Each individual file has an identical format. For convenience, this collection of files will be referred to as the *master* file, as though it was a single file. This will allow a reference to the *master* file to be understood to mean the *individual file* in the master.d directory that corresponds to the name of a device or module. The file is used by the *mkboot*(1M) program to obtain device information to generate the device driver and configurable module files. It is also used by the *sysdef*(1M) program to obtain the names of supported devices. *Master* consists of two parts; they are separated by a line with a dollar sign (\$) in column 1. Part 1 contains device information for both hardware and software devices, and loadable modules. Part 2 contains parameter declarations used in part 1. Any line with an asterisk (\*) in column 1 is treated as a comment.

### Part 1, Description

Hardware devices, software drivers and loadable modules are defined with a line containing the following information. Field 1 must begin in the left most position on the line. Fields are separated by white space (tab or blank).

	•			
Field 1:	element characterisitics:			
	0	specify only once		
	r	required device		
	b	block device		
	c	character device		
	a	generate segment descriptor array		
	t	initialize cdevsw[].d ttys		
	s	software driver		
	x	not a driver; a loadable module		
	number	The first interrupt vector for an integral		
		device		
Field 2:	number of ir	terrupt vectors required by a hardware dev-		
	ice: "-" if no			
Field 3:	handler prefi	x (4 chars. maximum)		
Field 4:	software driver external major number; "-" if not a			
	software driv			
Field 5:	number of sub-devices per device; "-" if none			
Field 6:	interrupt priority level of the device; "-" if none			
Field 7:	dependency list (optional); this is a comma separated			
		vers or modules that must be present in the		
		if this module is to be included		

For each module, two classes of information are required by mkboot(1M): external routine references and variable definitions. Routine and variable definition lines begin with white space and immediately follow the initial module specification line. These lines are free form, thus they may be continued arbitrarily between non-blank tokens as long as the first character of a line is white space.

# Part 1, Routine Reference Lines

If the UNIX system kernel or other dependent module contains external references to a module, but the module is not configured, then these external references would be undefined. Therefore, the *routine reference* lines are used to

MASTER (4) MASTER (4)

provide the information necessary to generate appropriate dummy functions at boot time when the driver is not loaded.

Routine references are defined as follows:

Field 1:

routine name ()

Field 2:

the routine type: one of

routine\_name(){}

{nosys} routine name() {return nosys();} {nodev} routine name() {return nodev();}

{false} routine name(){return 0;} {true} routine name() {return 1;}

# Part 1, Variable Definition Lines

Variable definition lines are used to generate all variables required by the module. The variable generated may be of arbitrary size, be initialized or not, or be arrays containing an arbitrary number of elements. variable references are defined as follows:

Field 1:

variable name

Field 2:

[ expr ] - optional field used to indicate array size

Field 3:

(length) - required field indicating the size of the vari-

Field 4:

={ expr,...} - optional field used to initialize individual elements of a variable

The length field is mandatory. It is an arbitrary sequence of length specifiers, each of which may be one of the following:

> %i %1

an integer

a long integer a short integer

%s %c

a single character

a field which is number bytes long

%number %number c

a character string which is number bytes long

For example, the length field

```
( %8c %l %0x58 %l %c %c )
```

could be used to identify a variable consistring of a character sting 8-bytes long, a long integer, a 0x58 byte structure of any type, another long integer, and two characters. Appropriate alignment of each % specification is performed (%number is word aligned) and the variable length is rounded up to the next word boundary during processing.

The expressions for the optional array size and initialization are infix expressions consisting of the usual operators for addition, subtraction, multiplication, and division: +, -, \*, and /. Multiplication and division have the higher precedence, but parentheses may be used to override the default order. The builtin functions min and max accept a pair of expressions, and return the appropriate value. The operands of the expression may be any mixture of the following:

&name

address of name where name is any symbol defined by

the kernel, any module loaded or any variable definition

line of any module loaded

#name

sizeof name where name is any variable name defined by a variable definition for any module loaded; the size is that of the individual variable--not the size of an entire

array

MASTER (4) MASTER (4)

> number of controllers present; this number is determined by the EDT for hardware devices, or by the number provided in the system file for non-hardware drivers or modules #C(name) number of controllers present for the module name; this number is determined by the EDT for hardware devices, or by the number provided in the system file for nonhardware drivers or modules #D number of devices per controller taken directly from the current master file entry #D(name) number of devices per controller taken directly from the master file entry for the module name #M the internal major number assigned to the current module if it is a device driver; zero of this module is not

a device driver

#C

string

#M(name) the internal major number assigned to the module name if it is a device driver: zero if that module is not a device

driver

value of a parameter as defined in the second part of name

master

number arbitrary number (octal, decimal, or hex allowed)

> a character string enclosed within double quotes (all of the character string conventions supported by the C language are allowed); this operand has a value which is the address of a character array containing the specified

When initializing a variable, one initialization expression should be provided for each %i, %l, %s, or %c of the length field. The only initializers allowed for a "number c' are either a character string (the string may not be longer than number), or an explicit zero. Initialization expressions must be separated by commas, and variable initialization will proceed element by element. Note that %number specification cannot be initialized--they are set to zero. Only the first element of an array can be initialized, the other elements are set to zero. If there are more initializers than size specifications, it is an error and execution of the mkboot (1M) program will be aborted. If there are fewer initializations than size specifications, zeros will be used to pad the variable. For example:

={ "V2.L1", #C\*#D, max(10,#D), #C(OTHER), #M(OTHER) }

would be a possible initialization of the variable whose length field was given in the preceeding example.

# Part 2, Description

Parameter declarations may be used to define a value symbolically. Values can be associated with identifiers and these identifiers may be used in the variable definition lines.

Parameters are defined as follows:

Field 1: identifier (8 characters maximum)

Field 2:

Field 3: value, the value may be a number (decimal, octal, or hex

allowed), or a string

MASTER (4) MASTER (4)

#### **EXAMPLE**

A sample *master* file for a tty device driver would be named "atty" if the device appeared in the EDT as "ATTY". The driver is a character device, the driver prefix is at, two interrupt vectors are used, and the interrupt priority is 6. In addition, another driver named "ATLOG" is necessary for the correct operation of the software associated with this device.

This master file will cause a routine named atpoint to be generated by the boot program if the ATTY driver is not loaded, and there is a reference to this routine from any other module loaded. When the driver is loaded, the variables at\_tty, at\_cnt, at\_logmaj, at\_id, and at\_table will be allocated and initialized as specified. Due to the t flag, the d\_ttys field in the character device switch table will be initialized to point to at\_tty (the first variable definition line contains the variable whose address will be stored in d\_ttys). The ATTY driver would reference these variables by coding:

```
extern struct tty at_tty[];
extern int at_cnt;
extern int at_logmaj;
extern char at id[8];
extern struct {
    int member1;
    struct tty *member2;
    char junk[31];
    short member3;
} at_table;
```

MNTTAB(4) MNTTAB(4)

NAME

mnttab - mounted file system table

### SYNOPSIS

#include <mnttab.h>

### DESCRIPTION

Mnttab resides in directory /etc and contains a table of devices, mounted by the mount (1M) command, in the following structure as defined by <mnttab.h>:

```
struct mnttab {
    char mt_dev[32];
    char mt_filsys[32];
    short mt_ro_flg;
    time_t mt_time;
};
```

Each entry is 70 bytes in length; the first 32 bytes are the null-padded name of the place where the *special file* is mounted; the next 32 bytes represent the null-padded root name of the mounted special file; the remaining 6 bytes contain the mounted *special file*'s read/write permissions and the date on which it was mounted.

The maximum number of entries in *mnttab* is based on the system parameter NMOUNT located in /usr/src/uts/cf/conf.c, which defines the number of allowable mounted special files.

#### SEE ALSO

mount(1M), setmnt(1M) in the 3B2 Computer System Administration Utilities Guide.

PASSWD(4) PASSWD(4)

NAME

passwd - password file

### DESCRIPTION

Passwd contains for each user the following information:

login name
encrypted password
numerical user ID
numerical group ID
GCOS job number, box number, optional GCOS user ID
initial working directory
program to use as shell

This is an ASCII file. Each field within each user's entry is separated from the next by a colon. The GCOS field is used only when communicating with that system, and in other installations can contain any desired information. Each user is separated from the next by a new-line. If the password field is null, no password is demanded; if the shell field is null, the shell itself is used.

This file resides in directory /etc. Because of the encrypted passwords, it can and does have general read permission and can be used, for example, to map numerical user IDs to names.

The encrypted password consists of 13 characters chosen from a 64-character alphabet (., /, 0-9,  $A-\mathbb{Z}$ ,  $a-\mathbb{Z}$ ), except when the password is null, in which case the encrypted password is also null. Password aging is effected for a particular user if his encrypted password in the password file is followed by a comma and a non-null string of characters from the above alphabet. (Such a string must be introduced in the first instance by the super-user.)

The first character of the age, M say, denotes the maximum number of weeks for which a password is valid. A user who attempts to login after his password has expired will be forced to supply a new one. The next character, m say, denotes the minimum period in weeks which must expire before the password may be changed. The remaining characters define the week (counted from the beginning of 1970) when the password was last changed. (A null string is equivalent to zero.) M and m have numerical values in the range 0-63 that correspond to the 64-character alphabet shown above (i.e., l = 1 week; l = 63 weeks). If l = 1 week; l = 63 weeks). If l = 1 week is password the next time he logs in (and the "age" will disappear from his entry in the password file). If l = 1 we sugar will disappear from his entry in the password file). If l = 1 we sugar will be string l = 1 only the super-user will be able to change the password.

PLOT(4) PLOT(4)

#### NAME

plot - graphics interface

#### DESCRIPTION

Files of this format are produced by routines described in plot(3X) and are interpreted for various devices by commands described in tplot(1G). A graphics file is a stream of plotting instructions. Each instruction consists of an ASCII letter usually followed by bytes of binary information. The instructions are executed in order. A point is designated by four bytes representing the x and y values; each value is a signed integer. The last designated point in an l, m, n, or p instruction becomes the "current point" for the next instruction.

Each of the following descriptions begins with the name of the corresponding routine in *plot* (3X).

m move: The next four bytes give a new current point.

- n cont: Draw a line from the current point to the point given by the next four bytes. See *tplot* (1G).
- p point: Plot the point given by the next four bytes.
- l line: Draw a line from the point given by the next four bytes to the point given by the following four bytes.
- t label: Place the following ASCII string so that its first character falls on the current point. The string is terminated by a new-line.
- e erase: Start another frame of output.
- f linemod: Take the following string, up to a new-line, as the style for drawing further lines. The styles are "dotted", "solid", "longdashed", "short-dashed", and "dotdashed". Effective only for the -T4014 and -Tver options of tplot (1G) (TEKTRONIX 4014 terminal and Versatec plotter).
- s space: The next four bytes give the lower left corner of the plotting area; the following four give the upper right corner. The plot will be magnified or reduced to fit the device as closely as possible.

Space settings that exactly fill the plotting area with unity scaling appear below for devices supported by the filters of *tplot* (1G). The upper limit is just outside the plotting area. In every case the plotting area is taken to be square; points outside may be displayable on devices whose face is not square.

```
DASI 300 space (0, 0, 4096, 4096);
DASI 300s space (0, 0, 4096, 4096);
DASI 450 space (0, 0, 4096, 4096);
TEKTRONIX 4014 space (0, 0, 3120, 3120);
Versatec plotter space (0, 0, 2048, 2048);
```

plot(3X), gps(4), term(5). graph(1G), tplot(1G) in the 3B2 Computer System Graphics Utilities Guide.

### WARNING

The plotting library plot (3X) and the curses library curses (3X) both use the names erase() and move(). The curses versions are macros. If you need both libraries, put the plot (3X) code in a different source file than the curses (3X) code, and/or #undef move() and erase() in the plot (3X) code.

PNCH(4) PNCH(4)

NAME

pnch - file format for card images

### DESCRIPTION

The PNCH format is a convenient representation for files consisting of card images in an arbitrary code.

A PNCH file is a simple concatenation of card records. A card record consists of a single control byte followed by a variable number of data bytes. The control byte specifies the number (which must lie in the range 0-80) of data bytes that follow. The data bytes are 8-bit codes that constitute the card image. If there are fewer than 80 data bytes, it is understood that the remainder of the card image consists of trailing blanks.

PROFILE(4) PROFILE(4)

#### NAME

profile - system-wide user profile

# **SYNOPSIS**

/etc/profile

### DESCRIPTION

All user who have the shell, sh(1), as their login command have the commands in this file included as part of the login sequence. It allows the system administrator to perform services for the entire user community. Typical services are the announcement of system news, user mail, and the setting of default environmental variables.

It is not unusual to have special actions for the root login or the su(1) command.

#### **FILES**

The file /etc/TIMEZONE is included early in the file to establish the default time zone.

### SEE ALSO

timezone(4).

sh(1) in the 3B2 Computer System User Reference Manual. su(1M) in the 3B2 Computer System Administration Utilities Guide.

#### **BUGS**

Care must be taken in providing system-wide services. One user's service is another's annoyance. Personal ".profile" files are better for serving all but the most global needs.

10/84 - 1 - 10/84

RELOC(4) RELOC(4)

NAME

reloc - relocation information for a common object file

**SYNOPSIS** 

```
#include <reloc.h>
```

# DESCRIPTION

Object files have one relocation entry for each relocatable reference in the text or data. If relocation information is present, it will be in the following format.

10/84

10/84

SCCSFILE(4) SCCSFILE(4)

NAME

sccsfile - format of SCCS file

#### DESCRIPTION

An SCCS file is an ASCII file. It consists of six logical parts: the *checksum*, the *delta table* (contains information about each delta), *user names* (contains login names and/or numerical group IDs of users who may add deltas), *flags* (contains definitions of internal keywords), *comments* (contains arbitrary descriptive information about the file), and the *body* (contains the actual text lines intermixed with control lines).

Throughout an SCCS file there are lines which begin with the ASCII SOH (start of heading) character (octal 001). This character is hereafter referred to as the control character and will be represented graphically as @. Any line described below which is not depicted as beginning with the control character is prevented from beginning with the control character.

Entries of the form DDDDD represent a five-digit string (a number between 00000 and 99999).

Each logical part of an SCCS file is described in detail below.

Checksum

The checksum is the first line of an SCCS file. The form of the line is:

@hDDDDD

The value of the checksum is the sum of all characters, except those of the first line. The **@h** provides a magic number of (octal) 064001.

Delta table

The delta table consists of a variable number of entries of the form:

The first line (@s) contains the number of lines inserted/deleted/unchanged, respectively. The second line (@d) contains the type of the delta (currently, normal: D, and removed: R), the SCCS ID of the delta, the date and time of creation of the delta, the login name corresponding to the real user ID at the time the delta was created, and the serial numbers of the delta and its predecessor, respectively.

The @i, @x, and @g lines contain the serial numbers of deltas included, excluded, and ignored, respectively. These lines are optional.

The @m lines (optional) each contain one MR number associated with the delta; the @c lines contain comments associated with the delta.

SCCSFILE(4) SCCSFILE(4)

The @e line ends the delta table entry.

User names

The list of login names and/or numerical group IDs of users who may add deltas to the file, separated by new-lines. The lines containing these login names and/or numerical group IDs are surrounded by the bracketing lines @u and @U. An empty list allows anyone to make a delta. Any line starting with a! prohibits the succeeding group or user from making deltas.

Flags

Keywords used internally (see *admin*(1) for more information on their use). Each flag line takes the form:

The following flags are defined:

@fz

@f t <type of program> @f v program name> @fi <keyword string> @fb @f m <module name> @ff <floor> @fc <ceiling> @f d <default-sid> @f n @fi @fl <lock-releases> @fq <user defined>

The t flag defines the replacement for the % Y% identification keyword. The v flag controls prompting for MR numbers in addition to comments; if the optional text is present it defines an MR number validity checking program. The i flag controls the warning/error aspect of the "No id keywords" message. When the i flag is not present, this message is only a warning; when the i flag is present, this message will cause a "fatal" error (the file will not be gotten, or the delta will not be made). When the b flag is present the -b keyletter may be used on the get command to cause a branch in the delta tree. The m flag defines the first choice for the replacement text of the %M% identification keyword. The f flag defines the "floor" release; the release below which no deltas may be added. The c flag defines the "ceiling" release; the release above which no deltas may be added. The d flag defines the default SID to be used when none is specified on a get command. The n flag causes delta to insert a "null" delta (a delta that applies no changes) in those releases that are skipped when a delta is made in a new release (e.g., when delta 5.1 is made after delta 2.7, releases 3 and 4 are skipped). The absence of the n flag causes skipped releases to be completely empty. The j flag causes get to allow concurrent edits of the same base SID. The I flag defines a list of releases that are locked against editing (get(1) with the -e keyletter). The q flag defines the replacement for the %Q% identification keyword. The z flag is used in certain specialized interface programs.

<reserved for use in interfaces>

SCCSFILE(4) SCCSFILE(4)

### Comments

Arbitrary text is surrounded by the bracketing lines @t and @T. The comments section typically will contain a description of the file's purpose.

Body

The body consists of text lines and control lines. Text lines do not begin with the control character, control lines do. There are three kinds of control lines: *insert*, *delete*, and *end*, represented by:

@I DDDDD @D DDDDD @E DDDDD

respectively. The digit string is the serial number corresponding to the delta for the control line.

SCNHDR(4) SCNHDR(4)

#### NAME

scnhdr - section header for a common object file

#### **SYNOPSIS**

#include <scnhdr.h>

#### DESCRIPTION

Every common object file has a table of section headers to specify the layout of the data within the file. Each section within an object file has its own header. The C structure appears below.

```
struct scnhdr
                       s name[SYMNMLEN]; /* section name */
       char
       long
                       s paddr;
                                   /* physical address */
                                   /* virtual address */
       long
                       s_vaddr;
                                   /* section size */
                       s size;
       long
                                   /* file ptr to raw data */
       long
                       s scnptr;
                       s relptr;
                                   /* file ptr to relocation */
       long
                       s lnnoptr;
                                   /* file ptr to line numbers */
       long
       unsigned short s nreloc;
                                   /* # reloc entries */
                                   /* # line number entries */
       unsigned short s nlnno;
                       s flags;
                                   /* flags */
};
```

File pointers are byte offsets into the file; they can be used as the offset in a call to fseek (3S). If a section is initialized, the file contains the actual bytes. An uninitialized section is somewhat different. It has a size, symbols defined in it, and symbols that refer to it. But it can have no relocation entries, line numbers, or data. Consequently, an uninitialized section has no raw data in the object file, and the values for s\_scnptr, s\_relptr, s\_lnnoptr, s\_nreloc, and s nlnno are zero.

SYMS(4) SYMS(4)

NAME

syms - common object file symbol table format

### **SYNOPSIS**

#include <syms.h>

#### DESCRIPTION

Common object files contain information to support *symbolic* software testing (see *sdb*(1)). Line number entries, *linenum*(4), and extensive symbolic information permit testing at the C *source* level. Every object file's symbol table is organized as shown below.

```
File name 1.
```

Function 1.

Local symbols for function 1.

Function 2.

Local symbols for function 2.

Static externs for file 1.

File name 2.

Function 1.

Local symbols for function 1.

Function 2.

Local symbols for function 2.

Static externs for file 2.

Defined global symbols. Undefined global symbols.

The entry for a symbol is a fixed-length structure. The members of the structure hold the name (null padded), its value, and other information. The C structure is given below.

```
#define SYMNMLEN
#define FILNMLEN
                        14
struct syment
                                  /* all ways to get symbol name */
   union
                     n name[SYMNMLEN]; /* symbol name */
      char
      struct
                     n_zeroes;
                                  /* == 0L when in string table */
         long
        long
                     n offset;
                                  /* location of name in table */
      } _n_n;
                     *_n_nptr[2]; /* allows overlaying */
      char
   } n;
                                  /* value of symbol */
   long
                     n value:
   short
                     n scnum;
                                  /* section number */
   unsigned short
                     n_type;
                                  /* type and derived type */
   char
                                  /* storage class */
                     n_sclass;
   char
                                  /* number of aux entries */
                     n_numaux;
};
#define n name
                    n. n name
```

SYMS(4) SYMS(4)

```
#define n_zeroes
#define n_offset
#define n nptr

n. n_n. n_zeroes
n. n_n. n_offset
n. n nptr[1]
```

Meaningful values and explanations for them are given in both syms.h and Common Object File Format. Anyone who needs to interpret the entries should seek more information in these sources. Some symbols require more information than a single entry; they are followed by auxiliary entries that are the same size as a symbol entry. The format follows.

```
union auxent
      struct
             long
                             x tagndx;
             union
                    struct
                             unsigned short x_lnno;
                             unsigned short x_size;
                    } x_lnsz;
                    long
                             x_fsize;
             } x misc;
             union
                    struct
                             long
                                    x_lnnoptr;
                             long
                                    x_endndx;
                             x fcn;
                    struct
                             unsigned short x dimen[DIMNUM];
                             x ary;
                             x fcnary;
             unsigned short x tvndx;
             x_sym;
      struct
                    x_fname[FILNMLEN];
             char
             x_file;
      struct
            long x scnlen;
            unsigned short x nreloc;
            unsigned short x_nlinno;
      }
            x_scn;
      struct
                             x tvfill;
             unsigned short x tylen;
             unsigned short x_tvran[2];
      }
             x tv;
};
```

SYMS(4) SYMS(4)

Indexes of symbol table entries begin at zero.

### SEE ALSO

### WARNINGS

On machines in which longs are equivalent to ints (3B20 computer, VAX), they are converted to ints in the compiler to minimize the complexity of the compiler code generator. Thus the information about which symbols are declared as longs and which, as ints, does not show up in the symbol table.

10/84 - 3 - 10/84

SYSTEM(4) SYSTEM(4)

NAME

system - system configuration information table

#### DESCRIPTION

This file is used by the **boot** program to obtain configuration information that cannot be obtained from the equipped device table (EDT) at system boot time. This file generally contains a list of software drivers to include in the load, the assignment of system devices such as *pipedev* and *swapdev*, as well as instructions for manually overriding the drivers selected by the self-configuring boot process.

The syntax of the system file is given below. The parser for the /etc/system file is case sensitive. All upper case strings in the syntax below should be upper case in the /etc/system file as well. Nonterminal symbols are enclosed in angle brackets "<>" while optional arguments are enclosed in square brackets "[]". Ellipses "..." indicate optional repetition of the argument for that line.

```
<fname> ::= pathname
<string> ::= driver file name from /boot or EDT entry name
<device> ::= special device name | DEV(<major>,<minor>)
<major> ::= <number>
<minor> ::= <number>
<number> ::= decimal, octal or hex literal
```

The lines listed below may appear in any order. Blank lines may be inserted at any point. Comment lines must begin with an asterisk. Entries for EXCLUDE and INCLUDE are cumulative. For all other entries, the last line to appear in the file is used -- any earlier entries are ignored.

BOOT: <fname>

specifies the kernel a.out file to be booted; if the file is fully resolved (such as that produced by the *mkunix*(1M) program) then all other lines in the *system* file have no effect.

EXCLUDE: [ <string> ] ...

specifies drivers to exclude from the load even if the device is found in the EDT.

INCLUDE: [ <string>[(<number>)] ]...

specifies software drivers or loadable modules to be included in the load. This is necessary to include the drivers for software "devices". The optional <number> (parenthesis required) specifies the number of "devices" to be controlled by the driver (defaults to 1). This number corresponds to the builtin variable #c which may be referred to by expressions in part one of the /etc/master file.

ROOTDEV: <device>

identifies the device containing the root file system.

SWAPDEV: <device> <number> <number>

identifies the device to be used as swap space, the block number the swap space starts at, and the number of swap blocks available.

PIPEDEV: <device>

identifies the device to be used for pipe space.

master(4). crash(1M), mkunix(1M), mkboot(1M) in the 3B2 Computer System Administration Utilities Guide.

TERM(4) TERM(4)

NAME

term - format of compiled term file.

SYNOPSIS

term

### DESCRIPTION

Compiled terminfo descriptions are placed under the directory /usr/lib/terminfo. In order to avoid a linear search of a huge UNIX system directory, a two-level scheme is used: /usr/lib/terminfo/c/name where name is the name of the terminal, and c is the first character of name. Thus, act4 can be found in the file /usr/lib/terminfo/a/act4. Synonyms for the same terminal are implemented by multiple links to the same compiled file.

The format has been chosen so that it will be the same on all hardware. An 8 or more bit byte is assumed, but no assumptions about byte ordering or sign extension are made.

The compiled file is created with the *compile* program, and read by the routine *setupterm*. Both of these pieces of software are part of *curses* (3X). The file is divided into six parts: the header, terminal names, boolean flags, numbers, strings, and string table.

The header section begins the file. This section contains six short integers in the format described below. These integers are (1) the magic number (octal 0432); (2) the size, in bytes, of the names section; (3) the number of bytes in the boolean section; (4) the number of short integers in the numbers section; (5) the number of offsets (short integers) in the strings section; (6) the size, in bytes, of the string table.

Short integers are stored in two 8-bit bytes. The first byte contains the least significant 8 bits of the value, and the second byte contains the most significant 8 bits. (Thus, the value represented is 256\*second+first.) The value -1 is represented by 0377, 0377, other negative value are illegal. The -1 generally means that a capability is missing from this terminal. Note that this format corresponds to the hardware of the VAX and PDP-11. Machines where this does not correspond to the hardware read the integers as two bytes and compute the result.

The terminal names section comes next. It contains the first line of the terminfo description, listing the various names for the terminal, separated by the 'character. The section is terminated with an ASCII NUL character.

The boolean flags have one byte for each flag. This byte is either 0 or 1 as the flag is present or absent. The capabilities are in the same order as the file <term.h>.

Between the boolean section and the number section, a null byte will be inserted, if necessary, to ensure that the number section begins on an even byte. All short integers are aligned on a short word boundary.

The numbers section is similar to the flags section. Each capability takes up two bytes, and is stored as a short integer. If the value represented is -1, the capability is taken to be missing.

The strings section is also similar. Each capability is stored as a short integer, in the format above. A value of -1 means the capability is missing. Otherwise, the value is taken as an offset from the beginning of the string table. Special characters in X or contation are stored in their interpreted form, not the printing representation. Padding information < and parameter information x are stored intact in uninterpreted form.

TERM(4) TERM(4)

The final section is the string table. It contains all the values of string capabilities referenced in the string section. Each string is null terminated.

Note that it is possible for *setupterm* to expect a different set of capabilities than are actually present in the file. Either the database may have been updated since *setupterm* has been recompiled (resulting in extra unrecognized entries in the file) or the program may have been recompiled more recently than the database was updated (resulting in missing entries). The routine *setupterm* must be prepared for both possibilities — this is why the numbers and sizes are included. Also, new capabilities must always be added at the end of the lists of boolean, number, and string capabilities.

As an example, an octal dump of the description for the Microterm ACT 4 is included:

```
microterm|act4|microterm act iv,
cr=^M, cud1=^J, ind=^J, bel=^G, am, cub1=^H,
ed=_, el=^^, clear=^L, cup=^T%p1%c%p2%c,
cols#80, lines#24, cuf1=^X, cuu1=^Z, home=^],
```

```
\0
000 032 001

3B2 Computer System Terminal Information Utilities Guide.

NAME

terminfo - terminal capability data base

#### SYNOPSIS

/usr/lib/terminfo/\*/\*

#### DESCRIPTION

Terminfo is a data base describing terminals, used, e.g., by vi(1) and curses(3X). Terminals are described in terminfo by giving a set of capabilities which they have, and by describing how operations are performed. Padding requirements and initialization sequences are included in terminfo.

Entries in terminfo consist of a number of ',' separated fields. White space after each ',' is ignored. The first entry for each terminal gives the names which are known for the terminal, separated by '|' characters. The first name given is the most common abbreviation for the terminal, the last name given should be a long name fully identifying the terminal, and all others are understood as synonyms for the terminal name. All names but the last should be in lower case and contain no blanks; the last name may well contain upper case and blanks for readability.

Terminal names (except for the last, verbose entry) should be chosen using the following conventions. The particular piece of hardware making up the terminal should have a root name chosen, thus "hp2621". This name should not contain hyphens, except that synonyms may be chosen that do not conflict with other names. Modes that the hardware can be in, or user preferences, should be indicated by appending a hyphen and an indicator of the mode. Thus, a vt100 in 132 column mode would be vt100-w. The following suffixes should be used where possible:

Suffix	Meaning	Example
-w	Wide mode (more than 80 columns)	vt100-w
-am	With auto. margins (usually default)	vt100-am
-nam	Without automatic margins	vt100-nam
-n	Number of lines on the screen	aaa-60
-na	No arrow keys (leave them in local)	c100-na
- <i>n</i> p	Number of pages of memory	c100-4p
-rv	Reverse video	c100-rv

### **CAPABILITIES**

The variable is the name by which the programmer (at the terminfo level) accesses the capability. The capname is the short name used in the text of the database, and is used by a person updating the database. The i.code is the two letter internal code used in the compiled database, and always corresponds to the old **termcap** capability name.

Capability names have no hard length limit, but an informal limit of 5 characters has been adopted to keep them short and to allow the tabs in the source file caps to line up nicely. Whenever possible, names are chosen to be the same as or similar to the ANSI X3.64-1979 standard. Semantics are also intended to match those of the specification.

- (P) indicates that padding may be specified
- (G) indicates that the string is passed through tparm with parms as given (#i).
- (\*) indicates that padding may be based on the number of lines affected
- (#;) indicates the i<sup>th</sup> parameter.

Variable Booleans	Cap- name	I. Code	Description
	bw	bw	ouhl wrong from column 0 to lost column
auto_left_margin,			cubl wraps from column 0 to last column
auto_right_margin, beehive glitch,	am xsb	am	Terminal has automatic margins
		xb	Beehive (f1=escape, f2=ctrl C)
ceol_standout_glitch,	xhp	xs	Standout not erased by overwriting (hp)
eat_newline_glitch,	xenl	xn	newline ignored after 80 cols (Concept)
erase_overstrike,	eo	eo	Can erase overstrikes with a blank
generic_type,	gn	gn	Generic line type (e.g.,, dialup, switch).
hard_copy,	hc	hc	Hardcopy terminal
has_meta_key,	km	km	Has a meta key (shift, sets parity bit)
has_status_line,	hs :	hs :	Has extra "status line"
insert_null_glitch,	in	in	Insert mode distinguishes nulls
memory_above,	da	da	Display may be retained above the screen
memory_below,	db :-	db :	Display may be retained below the screen
move_insert_mode,	mir	mi	Safe to move while in insert mode
move_standout_mode,	msgr	ms	Safe to move in standout modes
over_strike,	OS	os	Terminal overstrikes
status_line_esc_ok,	eslok	es	Escape can be used on the status line
teleray_glitch,	xt	xt	Tabs ruin, magic so char (Teleray 1061)
tilde_glitch,	hz	hz	Hazeltine; can not print "'s
transparent_underline,	ul	ul	underline character overstrikes
xon_xoff,	xon	xo	Terminal uses xon/xoff handshaking
Numbers:			
columns,	cols	co	Number of columns in a line
init_tabs,	it	it	Tabs initially every # spaces
lines,	lines	li	Number of lines on screen or page
lines_of_memory,	lm	lm	Lines of memory if > lines. 0 means varies
magic_cookie_glitch,	xmc	sg	Number of blank chars left by smso or rmso
padding_baud_rate,	pb	pb	Lowest baud where cr/nl padding is needed
virtual_terminal,	vt .	vt	Virtual terminal number (UNIX system)
width_status_line,	wsl	ws	No. columns in status line
Strings:		-	
back_tab,	cbt	bt	Back tab (P)
bell,	bel	bl	Audible signal (bell) (P)
carriage_return,	cr	cr	Carriage return (P*)
change_scroll_region,	csr	CS	change to lines #1 through #2 (vt100) (PG)
clear_all_tabs,	tbc	ct	Clear all tab stops (P)
clear_screen,	clear	cl	Clear screen and home cursor (P*)
clr_eol,	el	ce	Clear to end of line (P)
clr_eos,	ed	cd	Clear to end of display (P*)
column_address,	hpa	ch	Set cursor column (PG)
command_character,	cmdch	CC	Term. settable cmd char in prototype
cursor_address,	cup	cm	Screen rel. cursor motion row #1 col #2 (PG)
cursor_down,	cud1	do	Down one line
cursor_home,	home	ho	Home cursor (if no cup)
cursor_invisible,	civis	vi	Make cursor invisible
cursor_left,	cub1	le	Move cursor left one space
cursor_mem_address,	mrcup	CM	Memory relative cursor addressing
cursor_normal,	cnorm	ve	Make cursor appear normal (undo vs/vi)
cursor_right,	cufl	nd	Non-destructive space (cursor right)
cursor_to_ll,	11	11	Last line, first column (if no cup)
cursor_up,	cuul	up	Upline (cursor up)
cursor_visible,	cvvis	vs	Make cursor very visible
delete_character,	dch1	dc	Delete character (P*)

1 1 i P	11.1	-11	D 1 (D*)
delete_line,	dl1	dl	Delete line (P*)
dis_status_line,	dsl	ds	Disable status line
down_half_line,	hd	hd	Half-line down (forward 1/2 linefeed)
enter_alt_charset_mode,	smacs	as	Start alternate character set (P)
enter_blink_mode,	blink	mb	Turn on blinking
enter_bold_mode,	bold	md	Turn on bold (extra bright) mode
enter_ca_mode,	smcup	ti	String to begin programs that use cup
enter_delete_mode,	smdc	dm	Delete mode (enter)
enter_dim_mode,	dim	mh	Turn on half-bright mode
enter_insert_mode,	smir	im	Insert mode (enter);
enter_protected_mode,	prot	mp	Turn on protected mode
enter_reverse_mode,	rev	mr	Turn on reverse video mode
enter_secure_mode,	invis	mk	Turn on blank mode (chars invisible)
enter_standout_mode,	smso	so	Begin stand out mode
enter_underline_mode,	smul	us	Start underscore mode
erase_chars	ech	ec	Erase #1 characters (PG)
exit_alt_charset_mode,	rmacs	ae	End alternate character set (P)
exit_attribute_mode,	sgr0	me	Turn off all attributes
exit_ca_mode,	rmcup	te	String to end programs that use cup
exit_delete_mode,	rmdc	ed	End delete mode
exit_insert_mode,	rmir	ei	End insert mode
exit_standout_mode,	rmso	se	End stand out mode
exit_underline_mode,	rmul	ue	End underscore mode
flash_screen,	flash	vb	Visible bell (may not move cursor)
form_feed,	ff	ff	Hardcopy terminal page eject (P*)
from_status_line,	fsl	fs	Return from status line
init_1string,	is l	i1	Terminal initialization string
init_2string,	is2	i2	Terminal initialization string
init_3string,	is3	i3	Terminal initialization string
init_file,	if	if	Name of file containing is
insert_character,	ich1	ic	Insert character (P)
insert_line,	il1	al	Add new blank line (P*)
insert_padding,	ip	ip	Insert pad after character inserted (P*)
key_backspace,	kbs	kb	Sent by backspace key
key_catab,	ktbc	ka	Sent by clear-all-tabs key
key_clear,	kclr	kC	Sent by clear screen or erase key
key_ctab,	kctab	kt	Sent by clear-tab key
key_dc,	kdch1	kD	Sent by delete character key
key_dl,	kdl1	kL	Sent by delete line key
key_down,	kcud1	kd	Sent by terminal down arrow key
key_eic,	krmir	kM	Sent by rmir or smir in insert mode
key_eol,	kel	kE	Sent by clear-to-end-of-line key
key_eos,	ked	kS	Sent by clear-to-end-of-screen key
key_f0,	kf0	k0	Sent by function key f0
key_f1,	kf1	k1	Sent by function key f1
key_f10,	kf10	ka	Sent by function key f10
key_f2,	kf2	k2	Sent by function key f2
key_f3,	kf3	k3	Sent by function key f3
key_f4,	kf4	k4	Sent by function key f4
key_f5,	kf5	k5	Sent by function key f5
key_f6,	kf6	k6	Sent by function key f6
key_f7,	kf7	k7	Sent by function key f7
key_f8,	kf8	k8	Sent by function key f8
key_f9,	kf9	k9	Sent by function key f9
key_home,	khome	kh	Sent by home key
key_ic,	kich1	kI	Sent by ins char/enter ins mode key
key_il,	kil l	kA	Sent by insert line

1	1 1 . 4	1.1	0 - 1 - 11 0
key_left,	kcub1	kl	Sent by terminal left arrow key
key_ll,	kll	kH	Sent by home-down key
key_npage,	knp	kN	Sent by next-page key
key_ppage,	kpp	kP	Sent by previous-page key
key_right,	kcufl	kr	Sent by terminal right arrow key
key_sf,	kind	kF	Sent by scroll-forward/down key
key_sr,	kri	kR	Sent by scroll-backward/up key
key_stab,	khts	kT	Sent by set-tab key
key_up,	kcuu1	ku	Sent by terminal up arrow key
keypad_local,	rmkx	ke	Out of "keypad transmit" mode
keypad_xmit,	smkx	ks	Put terminal in "keypad transmit" mode
lab_f0,	1f0	10	Labels on function key f0 if not f0
lab_f1,	lf1	11	Labels on function key f1 if not f1
lab_f10,	lf10	la	Labels on function key f10 if not f10
lab_f2,	1f2	12	Labels on function key f2 if not f2
lab_f3,	lf3	13	Labels on function key f3 if not f3
lab_f4,	lf4	14	Labels on function key f4 if not f4
lab_f5,	lf5	15	Labels on function key f5 if not f5
lab_f6,	lf6	16	Labels on function key f6 if not f6
lab_f7,	1f7	17	Labels on function key f7 if not f7
lab_f8,	lf8	18	Labels on function key f8 if not f8
lab_f9,	1f9	19	Labels on function key f9 if not f9
meta_on,	smm	mm	Turn on "meta mode" (8th bit)
meta_off,	rmm	mo	Turn off "meta mode"
newline,	nel	nw	Newline (behaves like cr followed by lf)
pad_char,	pad	pc	Pad character (rather than null)
parm_dch,	dch	DC	Delete #1 chars (PG*)
parm_delete_line,	dl	DL	Delete #1 lines (PG*)
parm_down_cursor,	cud	DO	Move cursor down #1 lines (PG*)
parm_ich,	ich	IC	Insert #1 blank chars (PG*)
parm_index,	indn	SF	Scroll forward #1 lines (PG)
parm_insert_line,	il	AL	Add #1 new blank lines (PG*)
parm_left_cursor,	cub	LE	Move cursor left #1 spaces (PG)
parm_right_cursor,	cuf	RI	Move cursor right #1 spaces (PG*)
parm_rindex,	rin	SR	Scroll backward #1 lines (PG)
parm_up_cursor,	cuu	UP	Move cursor up #1 lines (PG*)
pkey_key,	pfkey	pk	Prog funct key #1 to type string #2
pkey_local,	pfloc	pl	Prog funct key #1 to execute string #2
pkey_xmit,	pfx	px	Prog funct key #1 to xmit string #2
print_screen,	mc0	ps	Print contents of the screen
prtr_off,	mc4	pf	Turn off the printer
prtr_on,	mc5	po	Turn on the printer
repeat_char,	rep	rp	Repeat char #1 #2 times. (PG*)
reset_lstring,	rs l	гl	Reset terminal completely to sane modes.
reset_2string,	rs2	r2	Reset terminal completely to sane modes.
reset_3string,	rs3	r3	Reset terminal completely to sane modes.
reset_file,	rf	rf	Name of file containing reset string
restore_cursor,	rc	rc	Restore cursor to position of last sc
row_address,	vpa	cv	Vertical position absolute (set row) (PG)
save_cursor,	sc	sc	Save cursor position (P)
scroll_forward,	ind	sf	Scroll text up (P)
scroll_reverse,	ri	sr	Scroll text down (P)
set_attributes,	sgr	sa	Define the video attributes (PG9)
set_tab,	hts	st	Set a tab in all rows, current column
set_window,	wind	wi	Current window is lines #1-#2 cols #3-#4
tab,	ht	ta	Tab to next 8 space hardware tab stop
to_status_line,	tsl	ts	Go to status line, column #1

underline_char,	uc	uc	Underscore one char and move past it
up_half_line,	hu	hu	Half-line up (reverse 1/2 linefeed)
init_prog,	iprog	iP	Path name of program for init
key_al,	ka l	K1	Upper left of keypad
key_a3,	ka3	K3	Upper right of keypad
key_b2,	kb2	K2	Center of keypad
key_c1,	kc1	K4	Lower left of keypad
key_c3,	kc3	K5	Lower right of keypad
prtr non,	mc5p	pO	Turn on the printer for #1 bytes

#### A Sample Entry

The following entry, which describes the Concept-100, is among the more complex entries in the *terminfo* file as of this writing.

```

```

Entries may continue onto multiple lines by placing white space at the beginning of each line except the first. Comments may be included on lines beginning with "#". Capabilities in *terminfo* are of three types: Boolean capabilities which indicate that the terminal has some particular feature, numeric capabilities giving the size of the terminal or the size of particular delays, and string capabilities, which give a sequence which can be used to perform particular terminal operations.

# Types of Capabilities

All capabilities have names. For instance, the fact that the Concept has automatic margins (i.e., an automatic return and linefeed when the end of a line is reached) is indicated by the capability am. Hence the description of the Concept includes am. Numeric capabilities are followed by the character '#' and then the value. Thus cols, which indicates the number of columns the terminal has, gives the value '80' for the Concept.

Finally, string valued capabilities, such as el (clear to end of line sequence) are given by the two-character code, an '=', and then a string ending at the next following ','. A delay in milliseconds may appear anywhere in such a capability, enclosed in \$<..> brackets, as in el=\EK\$<3>, and padding characters are supplied by tputs to provide this delay. The delay can be either a number, e.g., '20', or a number followed by an '\*', i.e., '3\*'. A '\*' indicates that the padding required is proportional to the number of lines affected by the operation, and the amount given is the per-affected-unit padding required. (In the case of insert character, the factor is still the number of lines affected. This is always one unless the terminal has xenl and the software uses it.) When a '\*' is specified, it is sometimes useful to give a delay of the form '3.5' to specify a delay per unit to tenths of milliseconds. (Only one decimal place is allowed.)

10/84 - 5 - 10/84

A number of escape sequences are provided in the string valued capabilities for easy encoding of characters there. Both  $\E$  and  $\e$  map to an ESCAPE character,  $\array{n}$  maps to a control-x for any appropriate x, and the sequences  $\array{n} \label{n} \label{n} \label{n} \label{n} \label{n} \array{n} \label{n} \array{n} \array{n}$ 

Sometimes individual capabilities must be commented out. To do this, put a period before the capability name. For example, see the second **ind** in the example above.

### **Preparing Descriptions**

We now outline how to prepare descriptions of terminals. The most effective way to prepare a terminal description is by imitating the description of a similar terminal in terminfo and to build up a description gradually, using partial descriptions with vi to check that they are correct. Be aware that a very unusual terminal may expose deficiencies in the ability of the terminfo file to describe it or bugs in vi. To easily test a new terminal description you can set the environment variable TERMINFO to a pathname of a directory containing the compiled description you are working on and programs will look there rather than in lusrlliblterminfo. To get the padding for insert line right (if the terminal manufacturer did not document it) a severe test is to edit /etc/passwd at 9600 baud, delete 16 or so lines from the middle of the screen, then hit the 'u' key several times quickly. If the terminal messes up, more padding is usually needed. A similar test can be used for insert character.

### **Basic Capabilities**

The number of columns on each line for the terminal is given by the cols numeric capability. If the terminal is a CRT, then the number of lines on the screen is given by the lines capability. If the terminal wraps around to the beginning of the next line when it reaches the right margin, then it should have the am capability. If the terminal can clear its screen, leaving the cursor in the home position, then this is given by the clear string capability. If the terminal overstrikes (rather than clearing a position when a character is struck over) then it should have the os capability. If the terminal is a printing terminal, with no soft copy unit, give it both hc and os. (os applies to storage scope terminals, such as TEKTRONIX 4010 series, as well as hard copy and APL terminals.) If there is a code to move the cursor to the left edge of the current row, give this as cr. (Normally this will be carriage return, control M.) If there is a code to produce an audible signal (bell, beep, etc) give this as bel.

If there is a code to move the cursor one position to the left (such as back-space) that capability should be given as **cub1**. Similarly, codes to move to the right, up, and down should be given as **cuf1**, **cuu1**, and **cud1**. These local cursor motions should not alter the text they pass over, for example, you would not normally use 'cuf1=' because the space would erase the character moved over.

A very important point here is that the local cursor motions encoded in *terminfo* are undefined at the left and top edges of a CRT terminal. Programs should never attempt to backspace around the left edge, unless **bw** is given, and never attempt to go up locally off the top. In order to scroll text up, a program will go to the bottom left corner of the screen and send the **ind** (index) string.

To scroll text down, a program goes to the top left corner of the screen and sends the ri (reverse index) string. The strings ind and ri are undefined when not on their respective corners of the screen.

Parameterized versions of the scrolling sequences are **indn** and **rin** which have the same semantics as **ind** and **ri** except that they take one parameter, and scroll that many lines. They are also undefined except at the appropriate edge of the screen.

The am capability tells whether the cursor sticks at the right edge of the screen when text is output, but this does not necessarily apply to a cuf1 from the last column. The only local motion which is defined from the left edge is if bw is given, then a cub1 from the left edge will move to the right edge of the previous row. If bw is not given, the effect is undefined. This is useful for drawing a box around the edge of the screen, for example. If the terminal has switch selectable automatic margins, the terminfo file usually assumes that this is on; i.e., am. If the terminal has a command which moves to the first column of the next line, that command can be given as nel (newline). It does not matter if the command clears the remainder of the current line, so if the terminal has no cr and If it may still be possible to craft a working nel out of one or both of them.

These capabilities suffice to describe hardcopy and glass-tty terminals. Thus the model 33 teletype is described as

```
33 | tty33 | tty | model 33 teletype,
bel=^G, cols#72, cr=^M, cud1=^J, hc, ind=^J, os,
while the Lear Siegler ADM-3 is described as
adm3 | 3 | 1si adm3,
am, bel=^G, clear=^Z, cols#80, cr=^M, cub1=^H, cud1=^J,
ind=^J, lines#24,
```

### **Parameterized Strings**

Cursor addressing and other strings requiring parameters in the terminal are described by a parameterized string capability, with printf(3S) like escapes % x in it. For example, to address the cursor, the cup capability is given, using two parameters: the row and column to address to. (Rows and columns are numbered from zero and refer to the physical screen visible to the user, not to any unseen memory.) If the terminal has memory relative cursor addressing, that can be indicated by **mrcup**.

The parameter mechanism uses a stack and special % codes to manipulate it. Typically a sequence will push one of the parameters onto the stack and then print it in some format. Often more complex operations are necessary.

The % encodings have the following meanings:

```
%%
                    outputs '%'
%d
                    print pop() as in printf
%2d
                    print pop() like %2d
%3d
                    print pop() like %3d
%02d
%03d
                    as in printf
%c
                    print pop() gives %c
                    print pop() gives %s
%s
%p[1-9]
                    push ith parm
%P[a-z]
                    set variable [a-z] to pop()
%g[a-z]
                    get variable [a-z] and push it
%'c'
                    char constant c
%{nn}
                    integer constant nn
%+ %- %* %/ %m
                    arithmetic (%m is mod): push(pop() op pop())
```

10/84 - 7 - 10/84

%& %| %^
bit operations: push(pop() op pop())
%= %> %
logical operations: push(pop() op pop())
%! %^
unary operations push(op pop())
add 1 to first two parms (for ANSI terminals)

%? expr %t thenpart %e elsepart %;
 if-then-else, %e elsepart is optional.
 else-if's are possible ala Algol 68:
 %? c<sub>1</sub> %t b<sub>1</sub> %e c<sub>2</sub> %t b<sub>2</sub> %e c<sub>3</sub> %t b<sub>3</sub> %e c<sub>4</sub> %t b<sub>4</sub> %e %;
 c; are conditions, b; are bodies.

Binary operations are in postfix form with the operands in the usual order. That is, to get x-5 one would use " $%gx%{5}$ ".

Consider the Hewlett-Packard 2645, which, to get to row 3 and column 12, needs to be sent \E&a12c03Y padded for 6 milliseconds. Note that the order of the rows and columns is inverted here, and that the row and column are printed as two digits. Thus its **cup** capability is cup=6\E&%p2%2dc%p1%2dY.

The Microterm ACT-IV needs the current row and column sent preceded by a ^T, with the row and column simply encoded in binary, cup=^T%p1%c%p2%c. Terminals which use %c need to be able to backspace the cursor (cub1), and to move the cursor up one line on the screen (cuu1). This is necessary because it is not always safe to transmit \n ^D and \r, as the system may change or discard them. (The library routines dealing with terminfo set tty modes so that tabs are never expanded, so \t is safe to send. This turns out to be essential for the Ann Arbor 4080.)

A final example is the LSI ADM-3a, which uses row and column offset by a blank character, thus cup=\E=\%p1\%' '\%+\%c\%p2\%' '\%+\%c. After sending '\E=', this pushes the first parameter, pushes the ASCII value for a space (32), adds them (pushing the sum on the stack in place of the two previous values) and outputs that value as a character. Then the same is done for the second parameter. More complex arithmetic is possible using the stack.

If the terminal has row or column absolute cursor addressing, these can be given as single parameter capabilities **hpa** (horizontal position absolute) and **vpa** (vertical position absolute). Sometimes these are shorter than the more general two parameter sequence (as with the hp2645) and can be used in preference to **cup**. If there are parameterized local motions (e.g., move *n* spaces to the right) these can be given as **cud**, **cub**, **cuf**, and **cuu** with a single parameter indicating how many spaces to move. These are primarily useful if the terminal does not have **cup**, such as the TEKTRONIX 4025.

# **Cursor Motions**

If the terminal has a fast way to home the cursor (to very upper left corner of screen) then this can be given as **home**; similarly a fast way of getting to the lower left-hand corner can be given as **ll**; this may involve going up with **cuu1** from the home position, but a program should never do this itself (unless **ll** does) because it can make no assumption about the effect of moving up from the home position. Note that the home position is the same as addressing to (0,0): to the top left corner of the screen, not of memory. (Thus, the \EH sequence on Hewlett-Packard terminals cannot be used for **home**.)

### Area Clears

If the terminal can clear from the current position to the end of the line, leaving the cursor where it is, this should be given as el. If the terminal can clear from the current position to the end of the display, then this should be given as ed. Ed is only defined from the first column of a line. (Thus, it can be simulated by a request to delete a large number of lines, if a true ed is not

10/84 - 8 - 10/84

available.)

### Insert/delete line

If the terminal can open a new blank line before the line where the cursor is, this should be given as il1; this is done only from the first position of a line. The cursor must then appear on the newly blank line. If the terminal can delete the line which the cursor is on, then this should be given as dl1; this is done only from the first position on the line to be deleted. Versions of il1 and dl1 which take a single parameter and insert or delete that many lines can be given as il and dl. If the terminal has a settable scrolling region (like the vt100) the command to set this can be described with the csr capability, which takes two parameters: the top and bottom lines of the scrolling region. The cursor position is, alas, undefined after using this command. It is possible to get the effect of insert or delete line using this command — the sc and rc (save and restore cursor) commands are also useful. Inserting lines at the top or bottom of the screen can also be done using ri or ind on many terminals without a true insert/delete line, and is often faster even on terminals with those features.

If the terminal has the ability to define a window as part of memory, which all commands affect, it should be given as the parameterized string wind. The four parameters are the starting and ending lines in memory and the starting and ending columns in memory, in that order.

If the terminal can retain display memory above, then the **da** capability should be given; if display memory can be retained below, then **db** should be given. These indicate that deleting a line or scrolling may bring non-blank lines up from below or that scrolling back with **ri** may bring down non-blank lines.

#### Insert/Delete Character

There are two basic kinds of intelligent terminals with respect to insert/delete character which can be described using terminfo. The most common insert/delete character operations affect only the characters on the current line and shift characters off the end of the line rigidly. Other terminals, such as the Concept 100 and the Perkin Elmer Owl, make a distinction between typed and untyped blanks on the screen, shifting upon an insert or delete only to an untyped blank on the screen which is either eliminated, or expanded to two untyped blanks. You can determine the kind of terminal you have by clearing the screen and then typing text separated by cursor motions. Type abc def using local cursor motions (not spaces) between the abc and the def. Then position the cursor before the abc and put the terminal in insert mode. If typing characters causes the rest of the line to shift rigidly and characters to fall off the end, then your terminal does not distinguish between blanks and untyped positions. If the abc shifts over to the def which then move together around the end of the current line and onto the next as you insert, you have the second type of terminal, and should give the capability in, which stands for insert null. While these are two logically separate attributes (one line vs. multiline insert mode, and special treatment of untyped spaces) we have seen no terminals whose insert mode cannot be described with the single attribute.

Terminfo can describe both terminals which have an insert mode, and terminals which send a simple sequence to open a blank position on the current line. Give as **smir** the sequence to get into insert mode. Give as **rmir** the sequence to leave insert mode. Now give as **ich1** any sequence needed to be sent just before sending the character to be inserted. Most terminals with a true insert mode will not give **ich1**; terminals which send a sequence to open a screen position should give it here. (If your terminal has both, insert mode is usually preferable to **ich1**. Do not give both unless the terminal actually requires both to be used in combination.) If post insert padding is needed, give this as a number of milliseconds in **ip** (a string option). Any other sequence which may need to be

sent after an insert of a single character may also be given in **ip**. If your terminal needs both to be placed into an 'insert mode' and a special code to precede each inserted character, then both **smir/rmir** and **ich1** can be given, and both will be used. The **ich** capability, with one parameter, n, will repeat the effects of **ich1** n times.

It is occasionally necessary to move around while in insert mode to delete characters on the same line (e.g., if there is a tab after the insertion position). If your terminal allows motion while in insert mode you can give the capability mir to speed up inserting in this case. Omitting mir will affect only speed. Some terminals (notably Datamedia's) must not have mir because of the way their insert mode works.

Finally, you can specify **dch1** to delete a single character, **dch** with one parameter, *n*, to delete *n* characters, and delete mode by giving **smdc** and **rmdc** to enter and exit delete mode (any mode the terminal needs to be placed in for **dch1** to work).

A command to erase n characters (equivalent to outputting n blanks without moving the cursor) can be given as **ech** with one parameter.

### Highlighting, Underlining, and Visible Bells

If your terminal has one or more kinds of display attributes, these can be represented in a number of different ways. You should choose one display form as *standout mode*, representing a good, high contrast, easy-on-the-eyes, format for highlighting error messages and other attention getters. (If you have a choice, reverse video plus half-bright is good, or reverse video alone.) The sequences to enter and exit standout mode are given as **smso** and **rmso**, respectively. If the code to change into or out of standout mode leaves one or even two blank spaces on the screen, as the TVI 912 and Teleray 1061 do, then **xmc** should be given to tell how many spaces are left.

Codes to begin underlining and end underlining can be given as **smul** and **rmul** respectively. If the terminal has a code to underline the current character and move the cursor one space to the right, such as the Microterm Mime, this can be given as **uc**.

Other capabilities to enter various highlighting modes include **blink** (blinking) **bold** (bold or extra bright) **dim** (dim or half-bright) **invis** (blanking or invisible text) **prot** (protected) **rev** (reverse video) **sgr0** (turn off *all* attribute modes) **smacs** (enter alternate character set mode) and **rmacs** (exit alternate character set mode). Turning on any of these modes singly may or may not turn off other modes.

If there is a sequence to set arbitrary combinations of modes, this should be given as sgr (set attributes), taking 9 parameters. Each parameter is either 0 or 1, as the corresponding attribute is on or off. The 9 parameters are, in order: standout, underline, reverse, blink, dim, bold, blank, protect, alternate character set. Not all modes need be supported by sgr, only those for which corresponding separate attribute commands exist.

Terminals with the "magic cookie" glitch (xme) deposit special "cookies" when they receive mode-setting sequences, which affect the display algorithm rather than having extra bits for each character. Some terminals, such as the Hewlett-Packard 2621, automatically leave standout mode when they move to a new line or the cursor is addressed. Programs using standout mode should exit standout mode before moving the cursor or sending a newline, unless the msgr capability, asserting that it is safe to move in standout mode, is present.

If the terminal has a way of flashing the screen to indicate an error quietly (a bell replacement) then this can be given as flash; it must not move the cursor.

If the cursor needs to be made more visible than normal when it is not on the bottom line (to make, for example, a non-blinking underline into an easier to find block or blinking underline) give this sequence as **cvvis**. If there is a way to make the cursor completely invisible, give that as **civis**. The capability **cnorm** should be given which undoes the effects of both of these modes.

If the terminal needs to be in a special mode when running a program that uses these capabilities, the codes to enter and exit this mode can be given as **smcup** and **rmcup**. This arises, for example, from terminals like the Concept with more than one page of memory. If the terminal has only memory relative cursor addressing and not screen relative cursor addressing, a one screen-sized window must be fixed into the terminal for cursor addressing to work properly. This is also used for the TEKTRONIX 4025, where **smcup** sets the command character to be the one used by terminfo.

If your terminal correctly generates underlined characters (with no special codes needed) even though it does not overstrike, then you should give the capability **ul**. If overstrikes are erasable with a blank, then this should be indicated by giving **eo**.

### Keypad

If the terminal has a keypad that transmits codes when the keys are pressed, this information can be given. Note that it is not possible to handle terminals where the keypad only works in local (this applies, for example, to the unshifted Hewlett-Packard 2621 keys). If the keypad can be set to transmit or not transmit, give these codes as smkx and rmkx. Otherwise the keypad is assumed to always transmit. The codes sent by the left arrow, right arrow, up arrow, down arrow, and home keys can be given as kcub1, kcuf1, kcuu1, kcud1, and khome respectively. If there are function keys such as f0, f1, ..., f10, the codes they send can be given as kf0, kf1, ..., kf10. If these keys have labels other than the default fo through f10, the labels can be given as Ifo, If1, ..., If10. The codes transmitted by certain other special keys can be given: kll (home down), kbs (backspace), ktbc (clear all tabs), kctab (clear the tab stop in this column), kclr (clear screen or erase key), kdch1 (delete character), kdl1 (delete line), krmir (exit insert mode), kel (clear to end of line), ked (clear to end of screen), kich1 (insert character or enter insert mode), kil1 (insert line), knp (next page), kpp (previous page), kind (scroll forward/down), kri (scroll backward/up), khts (set a tab stop in this column). In addition, if the keypad has a 3 by 3 array of keys including the four arrow keys, the other five keys can be given as ka1, ka3, kb2, kc1, and kc3. These keys are useful when the effects of a 3 by 3 directional pad are needed.

#### Tabs and Initialization

If the terminal has hardware tabs, the command to advance to the next tab stop can be given as **ht** (usually control I). A "backtab" command which moves leftward to the next tab stop can be given as **cht**. By convention, if the teletype modes indicate that tabs are being expanded by the computer rather than being sent to the terminal, programs should not use **ht** or **cht** even if they are present, since the user may not have the tab stops properly set. If the terminal has hardware tabs which are initially set every *n* spaces when the terminal is powered up, the numeric parameter **it** is given, showing the number of spaces the tabs are set to. This is normally used by the *tset* command to determine whether to set the mode for hardware tab expansion, and whether to set the tab stops. If the terminal has tab stops that can be saved in nonvolatile memory, the terminfo description can assume that they are properly set.

Other capabilities include is1, is2, and is3, initialization strings for the terminal, iprog, the path name of a program to be run to initialize the terminal, and if, the name of a file containing long initialization strings. These strings are

10/84 - 11 - 10/84

expected to set the terminal into modes consistent with the rest of the terminfo description. They are normally sent to the terminal, by the *tset* program, each time the user logs in. They will be printed in the following order: is1; is2; setting tabs using tbc and hts; if; running the program iprog; and finally is3. Most initialization is done with is2. Special terminal modes can be set up without duplicating strings by putting the common sequences in is2 and special cases in is1 and is3. A pair of sequences that does a harder reset from a totally unknown state can be analogously given as rs1, rs2, rf, and rs3, analogous to is2 and if. These strings are output by the *reset* program, which is used when the terminal gets into a wedged state. Commands are normally placed in rs2 and rf only if they produce annoying effects on the screen and are not necessary when logging in. For example, the command to set the vt100 into 80-column mode would normally be part of is2, but it causes an annoying glitch of the screen and is not normally needed since the terminal is usually already in 80 column mode.

If there are commands to set and clear tab stops, they can be given as **tbc** (clear all tab stops) and **hts** (set a tab stop in the current column of every row). If a more complex sequence is needed to set the tabs than can be described by this, the sequence can be placed in **is2** or **if**.

### Delays

Certain capabilities control padding in the teletype driver. These are primarily needed by hard copy terminals, and are used by the *tset* program to set teletype modes appropriately. Delays embedded in the capabilities **cr**, **ind**, **cub1**, **ff**, and **tab** will cause the appropriate delay bits to be set in the teletype driver. If **pb** (padding baud rate) is given, these values can be ignored at baud rates below the value of **pb**.

#### Miscellaneous

If the terminal requires other than a null (zero) character as a pad, then this can be given as pad. Only the first character of the pad string is used.

If the terminal has an extra "status line" that is not normally used by software, this fact can be indicated. If the status line is viewed as an extra line below the bottom line, into which one can cursor address normally (such as the Heathkit h19's 25th line, or the 24th line of a vt100 which is set to a 23-line scrolling region), the capability hs should be given. Special strings to go to the beginning of the status line and to return from the status line can be given as tsl and fsl. (fsl must leave the cursor position in the same place it was before tsl. If necessary, the sc and rc strings can be included in tsl and fsl to get this effect.) The parameter tsl takes one parameter, which is the column number of the status line the cursor is to be moved to. If escape sequences and other special commands, such as tab, work while in the status line, the flag eslok can be given. A string which turns off the status line (or otherwise erases its contents) should be given as dsl. If the terminal has commands to save and restore the position of the cursor, give them as sc and rc. The status line is normally assumed to be the same width as the rest of the screen, e.g., cols. If the status line is a different width (possibly because the terminal does not allow an entire line to be loaded) the width, in columns, can be indicated with the numeric parameter wsl.

If the terminal can move up or down half a line, this can be indicated with hu (half-line up) and hd (half-line down). This is primarily useful for superscripts and subscripts on hardcopy terminals. If a hardcopy terminal can eject to the next page (form feed), give this as ff (usually control L).

If there is a command to repeat a given character a given number of times (to save time transmitting a large number of identical characters) this can be

indicated with the parameterized string rep. The first parameter is the character to be repeated and the second is the number of times to repeat it. Thus, tparm(repeat char, 'x', 10) is the same as 'xxxxxxxxxxx'.

If the terminal has a settable command character, such as the TEKTRONIX 4025, this can be indicated with **cmdch**. A prototype command character is chosen which is used in all capabilities. This character is given in the **cmdch** capability to identify it. The following convention is supported on some UNIX systems: The environment is to be searched for a CC variable, and if found, all occurrences of the prototype character are replaced with the character in the environment variable.

Terminal descriptions that do not represent a specific kind of known terminal, such as *switch*, *dialup*, *patch*, and *network*, should include the **gn** (generic) capability so that programs can complain that they do not know how to talk to the terminal. (This capability does not apply to *virtual* terminal descriptions for which the escape sequences are known.)

If the terminal uses xon/xoff handshaking for flow control, give xon. Padding information should still be included so that routines can make better decisions about costs, but actual pad characters will not be transmitted.

If the terminal has a "meta key" which acts as a shift key, setting the 8th bit of any character transmitted, this fact can be indicated with km. Otherwise, software will assume that the 8th bit is parity and it will usually be cleared. If strings exist to turn this "meta mode" on and off, they can be given as smm and rmm.

If the terminal has more lines of memory than will fit on the screen at once, the number of lines of memory can be indicated with lm. A value of lm#0 indicates that the number of lines is not fixed, but that there is still more memory than fits on the screen.

If the terminal is one of those supported by the UNIX system virtual terminal protocol, the terminal number can be given as vt.

Media copy strings which control an auxiliary printer connected to the terminal can be given as mc0: print the contents of the screen, mc4: turn off the printer, and mc5: turn on the printer. When the printer is on, all text sent to the terminal will be sent to the printer. It is undefined whether the text is also displayed on the terminal screen when the printer is on. A variation mc5p takes one parameter, and leaves the printer on for as many characters as the value of the parameter, then turns the printer off. The parameter should not exceed 255. All text, including mc4, is transparently passed to the printer while an mc5p is in effect.

Strings to program function keys can be given as pfkey, pfloc, and pfx. Each of these strings takes two parameters: the function key number to program (from 0 to 10) and the string to program it with. Function key numbers out of this range may program undefined keys in a terminal dependent manner. The difference between the capabilities is that pfkey causes pressing the given key to be the same as the user typing the given string; pfloc causes the string to be executed by the terminal in local; and pfx causes the string to be transmitted to the computer.

10/84 - 13 - 10/84

# Glitches and Braindamage

Hazeltine terminals, which do not allow '" characters to be displayed should indicate hz.

Terminals which ignore a linefeed immediately after an **am** wrap, such as the Concept and vt100, should indicate **xenl**.

If el is required to get rid of standout (instead of merely writing normal text on top of it), **xhp** should be given.

Teleray terminals, where tabs turn all characters moved over to blanks, should indicate xt (destructive tabs). This glitch is also taken to mean that it is not possible to position the cursor on top of a "magic cookie", that to erase standout mode it is instead necessary to use delete and insert line.

The Beehive Superbee, which is unable to correctly transmit the escape or control C characters, has **xsb**, indicating that the f1 key is used for escape and f2 for control C. (Only certain Superbees have this problem, depending on the ROM.)

Other specific terminal problems may be corrected by adding more capabilities of the form xx.

#### Similar Terminals

If there are two very similar terminals, one can be defined as being just like the other with certain exceptions. The string capability use can be given with the name of the similar terminal. The capabilities given before use override those in the terminal type invoked by use. A capability can be cancelled by placing xx@ to the left of the capability definition, where xx is the capability. For example, the entry

2621-nl, smkx@, rmkx@, use=2621,

defines a 2621-nl that does not have the **smkx** or **rmkx** capabilities, and hence does not turn on the function key labels when in visual mode. This is useful for different modes for a terminal, or for different user preferences.

TIMEZONE(4) TIMEZONE(4)

NAME

timezone - set default system time zone

**SYNOPSIS** 

/etc/TIMEZONE

# DESCRIPTION

This file sets and exports the time zone environmental variable TZ. This file is "dotted" into other files that must know the time zone.

# **EXAMPLES**

/etc/TIMEZONE for the east coast:

# Time Zone TZ=EST5EDT export TZ

# SEE ALSO

```
NAME
        utmp, wtmp - utmp and wtmp entry formats
SYNOPSIS
        #include <sys/types.h>
        #include <utmp.h>
DESCRIPTION
        These files, which hold user and accounting information for such commands as
        who(1), write(1), and login(1), have the following structure as defined by
        <utmp.h>:
        l lp-1 l.
        #define UTMP FILE
                                "/etc/utmp"
        #define WTMP FILE
                                "/etc/wtmp"
        111.
        #define ut_name
                                ut user
        11 11 11 1.
        struct
               utmp {
                char
                        ut user[8];
                                        /* User login name */
                char
                        ut_id[4];
                                        /* /etc/inittab id (usually line #) */
                        ut line[12];
                                        /* device name (console, lnxx) */
                char
                       ut_pid; /* process id */
ut_type; /* type of entry */
                short
                short
                struct exit status {
                  short
                          e termination;
                                                /* Process termination status */
                  short
                                        /* Process exit status */
                           e exit;
                } ut_exit;
                                        /* The exit status of a process
                                * marked as DEAD PROCESS. */
                time t ut time; /* time entry was made */
       };

ENVIRON(5) ENVIRON(5)

#### NAME

environ - user environment

#### DESCRIPTION

An array of strings called the "environment" is made available by exec (2) when a process begins. By convention, these strings have the form "name=value". The following names are used by various commands:

PATH The sequence of directory prefixes that sh(1), time(1), nice(1), nohup(1), etc., apply in searching for a file known by an incomplete path name. The prefixes are separated by colons (:). Login(1) sets PATH = :/bin:/usr/bin.

**HOME** Name of the user's login directory, set by login(1) from the password file passwd(4).

TERM The kind of terminal for which output is to be prepared. This information is used by commands, such as mm(1) or tplot(1G), which may exploit special capabilities of that terminal.

TZ Time zone information. The format is xxxnzzz where xxx is standard local time zone abbreviation, n is the difference in hours from GMT, and zzz is the abbreviation for the daylight-saving local time zone, if any; for example, EST5EDT.

Further names may be placed in the environment by the *export* command and "name=value" arguments in sh(1), or by exec(2). It is unwise to conflict with certain shell variables that are frequently exported by **.profile** files: MAIL, PS1, PS2, IFS.

MATH(5) MATH(5)

NAME

math - math functions and constants

### **SYNOPSIS**

#include < math.h>

### DESCRIPTION

This file contains declarations of all the functions in the Math Library (described in Section 3M), as well as various functions in the C Library (Section 3C) that return floating-point values.

It defines the structure and constants used by the matherr (3M) error-handling mechanisms, including the following constant used as an error-return value:

HUGE

The maximum value of a single-precision floating-point

number.

The following mathematical constants are defined for user convenience:

M E

The base of natural logarithms (e).

M\_LOG2E

The base-2 logarithm of e.

The base-10 logarithm of e.

M LOG10E M LN2

The natural logarithm of 2.

M\_LN10

The natural logarithm of 10.

M PI

 $\pi$ , the ratio of the circumference of a circle to its diameter. (There are also several fractions of  $\pi$ , its reciprocal,

and its square root.)

M\_SQRT2

The positive square root of 2.

M SQRT1 2

The positive square root of 1/2.

For the definitions of various machine-dependent "constants," see the description of the <values.h> header file.

#### **FILES**

### SEE ALSO

intro(3), matherr(3M), values(5).

PROF(5) PROF(5)

#### **NAME**

prof - profile within a function

### SYNOPSIS

#define MARK #include <prof.h> void MARK (name)

### DESCRIPTION

MARK will introduce a mark called *name* that will be treated the same as a function entry point. Execution of the mark will add to a counter for that mark, and program-counter time spent will be accounted to the immediately preceding mark or to the function if there are no preceding marks within the active function.

Name may be any combination of up to six letters, numbers or underscores. Each name in a single compilation must be unique, but may be the same as any ordinary program symbol.

For marks to be effective, the symbol MARK must be defined before the header file < prof.h > is included. This may be defined by a preprocessor directive as in the synopsis, or by a command line argument, i.e:

```
cc -p -DMARK foo.c
```

If MARK is not defined, the MARK (name) statements may be left in the source files containing them and will be ignored.

### **EXAMPLE**

In this example, marks can be used to determine how much time is spent in each loop. Unless this example is compiled with MARK defined on the command line, the marks are ignored.

```
#include <prof.h>

foo()
{
    int i, j;
    ...
    ...
    MARK(loop1);
    for (i = 0; i < 2000; i++) {
        ...
    }
    MARK(loop2);
    for (j = 0; j < 2000; j++) {
        ...
    }
}
```

REGEXP(5) REGEXP(5)

#### NAME

regexp - regular expression compile and match routines

### **SYNOPSIS**

#define INIT <declarations>
#define GETC() <getc code>
#define PEEKC() <peekc code>
#define UNGETC(c) <ungetc code>
#define RETURN(pointer) <return code>
#define ERROR(val) <error code>
#include <regexp.h>
char \*compile (instring, expbuf, endbuf, eof)
char \*instring, \*expbuf, \*endbuf;
int eof;
int step (string, expbuf)
char \*string, \*expbuf;
extern char \*loc1, \*loc2, \*locs;

extern int circf, sed, nbra;

### DESCRIPTION

PEEKC()

This page describes general-purpose regular expression matching routines in the form of ed(1), defined in /usr/include/regexp.h. Programs such as ed(1), sed(1), grep(1), bs(1), expr(1), etc., which perform regular expression matching use this source file. In this way, only this file need be changed to maintain regular expression compatibility.

The interface to this file is unpleasantly complex. Programs that include this file must have the following five macros declared before the "#include <regexp.h>" statement. These macros are used by the compile routine.

GETC() Return the value of the next character in the regular

expression pattern. Successive calls to GETC() should return successive characters of the regular expression.

Return the next character in the regular expression.

Successive calls to PEEKC() should return the same character (which should also be the next character

returned by GETC()).

UNGETC(c) Cause the argument c to be returned by the next call to

GETC() (and PEEKC()). No more that one character of pushback is ever needed and this character is guaranteed to be the last character read by GETC(). The value of the macro UNGETC(c) is always ignored.

RETURN(pointer) This macro is used on normal exit of the compile rou-

tine. The value of the argument *pointer* is a pointer to the character after the last character of the compiled regular expression. This is useful to programs which

have memory allocation to manage.

ERROR(val) This is the abnormal return from the compile routine.

The argument val is an error number (see table below

for meanings). This call should never return.

REGEXP(5) REGEXP(5)

<b>ERROR</b>	MEANING
11	Range endpoint too large.
16	Bad number.
25	"\digit" out of range.
36	Illegal or missing delimiter.
41	No remembered search string.
42	\(\) imbalance.
43	Too many \(.
44	More than 2 numbers given in $\setminus \{ \setminus \}$ .
45	} expected after \.
46	First number exceeds second in $\setminus \{ \ \ \}$ .
49	[] imbalance.
50	Regular expression overflow.

The syntax of the compile routine is as follows:

compile(instring, expbuf, endbuf, eof)

The first parameter *instring* is never used explicitly by the *compile* routine but is useful for programs that pass down different pointers to input characters. It is sometimes used in the INIT declaration (see below). Programs which call functions to input characters or have characters in an external array can pass down a value of ((char \*) 0) for this parameter.

The next parameter *expbuf* is a character pointer. It points to the place where the compiled regular expression will be placed.

The parameter *endbuf* is one more than the highest address where the compiled regular expression may be placed. If the compiled expression cannot fit in (*endbuf*-*expbuf*) bytes, a call to ERROR(50) is made.

The parameter eof is the character which marks the end of the regular expression. For example, in ed(1), this character is usually a I.

Each program that includes this file must have a #define statement for INIT. This definition will be placed right after the declaration for the function compile and the opening curly brace ({). It is used for dependent declarations and initializations. Most often it is used to set a register variable to point the beginning of the regular expression so that this register variable can be used in the declarations for GETC(), PEEKC() and UNGETC(). Otherwise it can be used to declare external variables that might be used by GETC(), PEEKC() and UNGETC(). See the example below of the declarations taken from grep(1).

There are other functions in this file which perform actual regular expression matching, one of which is the function *step*. The call to *step* is as follows:

### step(string, expbuf)

The first parameter to *step* is a pointer to a string of characters to be checked for a match. This string should be null terminated.

The second parameter *expbuf* is the compiled regular expression which was obtained by a call of the function *compile*.

The function *step* returns non-zero if the given string matches the regular expression, and zero if the expressions do not match. If there is a match, two external character pointers are set as a side effect to the call to *step*. The variable set in *step* is *loc1*. This is a pointer to the first character that matched the regular expression. The variable *loc2*, which is set by the function *advance*, points to the character after the last character that matches the regular expression. Thus if the regular expression matches the entire line, *loc1* will point to the first character of *string* and *loc2* will point to the null at the end of *string*.

REGEXP(5) REGEXP(5)

Step uses the external variable circf which is set by compile if the regular expression begins with ^. If this is set then step will try to match the regular expression to the beginning of the string only. If more than one regular expression is to be compiled before the first is executed the value of circf should be saved for each compiled expression and circf should be set to that saved value before each call to step.

The function advance is called from step with the same arguments as step. The purpose of step is to step through the string argument and call advance until advance returns non-zero indicating a match or until the end of string is reached. If one wants to constrain string to the beginning of the line in all cases, step need not be called; simply call advance.

When advance encounters a \* or  $\{\ \ \}$  sequence in the regular expression, it will advance its pointer to the string to be matched as far as possible and will recursively call itself trying to match the rest of the string to the rest of the regular expression. As long as there is no match, advance will back up along the string until it finds a match or reaches the point in the string that initially matched the \* or  $\{\ \ \ \}$ . It is sometimes desirable to stop this backing up before the initial point in the string is reached. If the external character pointer locs is equal to the point in the string at sometime during the backing up process, advance will break out of the loop that backs up and will return zero. This is used by ed(1) and sed(1) for substitutions done globally (not just the first occurrence, but the whole line) so, for example, expressions like s/y\*//g do not loop forever.

The additional external variables sed and nbra are used for special purposes.

### **EXAMPLES**

The following is an example of how the regular expression macros and calls look from grep (1):

```
#define INIT
                          register char *sp = instring;
#define GETC()
                          (*sp++)
#define PEEKC()
                           (*sp)
#define UNGETC(c)
                           (--sp)
#define RETURN(c)
                          return;
#define ERROR(c)
                          regerr()
#include <regexp.h>
                 (void) compile(*argv, expbuf, &expbuf[ESIZE], \0');
                 if (step(linebuf, expbuf))
                                  succeed();
```

### **FILES**

### BUGS

The handling of circf is kludgy.

The actual code is probably easier to understand than this manual page.

```
NAME
```

stat - data returned by stat system call

### SYNOPSIS

```
#include <sys/types.h>
#include <sys/stat.h>
```

## DESCRIPTION

The system calls stat and fstat return data whose structure is defined by this include file. The encoding of the field  $st\_mode$  is defined in this file also.

```
* Structure of the result of stat
 */
struct
         stat
         dev t
                  st dev;
         ino_t
                  st ino;
                  st_mode;
         ushort
         short
                  st_nlink;
         ushort
                  st uid;
         ushort
                  st_gid;
         dev t
                  st rdev;
         off t
                  st size;
         time t
                  st atime;
         time t
                  st mtime;
         time t
                  st_ctime;
};
#define S_IFMT
                   0170000 /* type of file */

TERM(5) TERM(5)

#### NAME

term - conventional names for terminals

### DESCRIPTION

These names are used by certain commands (e.g., tabs(1) is maintained as part of the shell environment (see sh(1), profile(4), and environ(5)) in the variable **STERM**:

```
1520
           Datamedia 1520
 1620
           DIABLO 1620 and others using the HyType II printer
1620 - 12
          same, in 12-pitch mode
2621
           Hewlett-Packard 2621 series
2631
           Hewlett-Packard 2631 line printer
           Hewlett-Packard 2631 line printer - compressed mode
2631-c
           Hewlett-Packard 2631 line printer - expanded mode
2631-e
2640
           Hewlett-Packard 2640 series
           Hewlett-Packard 264n series (other than the 2640 series)
2645
           DASI/DTC/GSI 300 and others using the HyType I printer
300
300 - 12
          same, in 12-pitch mode
300s
          DASI/DTC/GSI 300s
382
          DTC 382
300s-12
          same, in 12-pitch mode
3045
          Datamedia 3045
33
          TELETYPE® Model 33 KSR
37
          TELETYPE Model 37 KSR
40 - 2
          TELETYPE Model 40/2
40-4
          TELETYPE Model 40/4
4540
          TELETYPE Model 4540
3270
          IBM Model 3270
4000a
          Trendata 4000a
4014
          TEKTRONIX 4014
43
          TELETYPE Model 43 KSR
450
          DASI 450 (same as Diablo 1620)
450-12
          same, in 12-pitch mode
735
          Texas Instruments T1735 and T1725
745
          Texas Instruments T1745
          generic name for terminals that lack reverse
dumb
          line-feed and other special escape sequences
sync
          generic name for synchronous TELETYPE
          4540-compatible terminals
hp
          Hewlett-Packard (same as 2645)
lp
          generic name for a line printer
tn1200
          User Electric TermiNet 1200
tn300
          User Electric TermiNet 300
```

Up to 8 characters, chosen from [-a-z0-9], make up a basic terminal name. Terminal sub-models and operational modes are distinguished by suffixes beginning with a -. Names should generally be based on original vendors, rather than local distributors. A terminal acquired from one vendor should not have more than one distinct basic name.

Commands whose behavior depends on the type of terminal should accept arguments of the form -Tterm where term is one of the names given above; if no such argument is present, such commands should obtain the terminal type from the environment variable \$TERM, which, in turn, should contain term.

### **BUGS**

This is a small candle trying to illuminate a large, dark problem. Programs that ought to adhere to this nomenclature do so somewhat fitfully.

TYPES(5) TYPES(5)

NAME

types - primitive system data types

### **SYNOPSIS**

#include <sys/types.h>

### DESCRIPTION

The data types defined in the include file are used in UNIX system code; some data of these types are accessible to user code:

```
typedef struct { int r[1]; } *
                                           physadr;
typedef long
                        daddr t;
typedef char *
                        caddr t;
typedef unsigned int
                        uint;
typedef unsigned short ushort;
typedef ushort
                        ino t;
typedef short
                        cnt t;
typedef long
                        time t;
typedef int
                        label t[10];
typedef short
                        dev t;
typedef long
                        off t;
typedef long
                        paddr t;
typedef long
                        key t;
```

The form  $daddr_t$  is used for disk addresses except in an i-node on disk, see fs(4). Times are encoded in seconds since 00:00:00 GMT, January 1, 1970. The major and minor parts of a device code specify kind and unit number of a device and are installation-dependent. Offsets are measured in bytes from the beginning of a file. The  $label_t$  variables are used to save the processor state while another process is running.

### SEE ALSO

fs(4).

VALUES (5) VALUES (5)

### **NAME**

values - machine-dependent values

### SYNOPSIS

#include <values.h>

### DESCRIPTION

This file contains a set of manifest constants, conditionally defined for particular processor architectures.

The model assumed for integers is binary representation (one's or two's complement), where the sign is represented by the value of the high-order bit.

BITS(type)

The number of bits in a specified type (e.g., int).

HIBITS

The value of a short integer with only the high-order bit

set (in most implementations, 0x8000).

HIBITL

The value of a long integer with only the high-order bit

set (in most implementations, 0x80000000).

HIBITI

The value of a regular integer with only the high-order

bit set (usually the same as HIBITS or HIBITL).

MAXSHORT

The maximum value of a signed short integer (in most

implementations,  $0x7FFF \equiv 32767$ ).

MAXLONG

The maximum value of a signed long integer (in most

implementations,  $0x7FFFFFFF \equiv 2147483647$ ).

MAXINT

The maximum value of a signed regular integer (usually

the same as MAXSHORT or MAXLONG).

MAXFLOAT, LN\_MAXFLOAT

The maximum value of a single-precision floating-point number, and its natural loga-

rithm.

MAXDOUBLE, LN\_MAXDOUBLE The maximum value of a double-precision floating-point number, and its natural loga-

rithm.

MINFLOAT, LN MINFLOAT

The minimum positive value of a singleprecision floating-point number, and its

natural logarithm.

MINDOUBLE, LN MINDOUBLE

The minimum positive value of a doubleprecision floating-point number, and its

natural logarithm.

**FSIGNIF** 

The number of significant bits in the mantissa of a

single-precision floating-point number.

DSIGNIF

The number of significant bits in the mantissa of a

double-precision floating-point number.

VARARGS(5) VARARGS(5)

### NAME

varargs - handle variable argument list

#### SYNOPSIS

```
#include <varargs.h>
va_alist
va_dcl
void va_start(pvar)
va_list pvar;
type va_arg(pvar, type)
va_list pvar;
void va_end(pvar)
va_list pvar;
```

### DESCRIPTION

This set of macros allows portable procedures that accept variable argument lists to be written. Routines that have variable argument lists (such as printf(3S)) but do not use varargs are inherently nonportable, as different machines use different argument-passing conventions.

va\_alist is used as the parameter list in a function header.

va\_dcl is a declaration for va\_alist. No semicolon should follow va dcl.

va\_list is a type defined for the variable used to traverse the list.

va\_start is called to initialize pvar to the beginning of the list.

va\_arg will return the next argument in the list pointed to by pvar. Type is the type the argument is expected to be. Different types can be mixed, but it is up to the routine to know what type of argument is expected, as it cannot be determined at runtime.

va\_end is used to clean up.

#include <varargs.h>

Multiple traversals, each bracketed by va\_start ... va\_end, are possible.

### **EXAMPLE**

This example is a possible implementation of exect(2).

```
#define MAXARGS
                         100
/*
        execl is called by
                 execl(file, arg1, arg2, ..., (char *)0);
*/
execl(va alist)
va dcl
        va list ap;
        char *file;
        char *args[MAXARGS];
        int argno = 0;
        va start(ap);
        file = va arg(ap, char *);
        while ((args[argno++] = va_arg(ap, char *)) != (char *)0)
        va end(ap);
        return execv(file, args);
}
```

VARARGS(5) VARARGS(5)

**SEE ALSO** 

exec(2), printf(3S).

**BUGS** 

It is up to the calling routine to specify how many arguments there are, since it is not always possible to determine this from the stack frame. For example, *execl* is passed a zero pointer to signal the end of the list. *Printf* can tell how many arguments are there by the format.

It is non-portable to specify a second argument of *char*, *short*, or *float* to  $va\_arg$ , since arguments seen by the called function are not *char*, *short*, or *float*. C converts *char* and *short* arguments to *int* and converts *float* arguments to *double* before passing them to a function.
